Chapter 1

Introduction

This document describes an implementation of Genz (1992) and, partially, of Genz and Bretz (2002), for the evaluation of N multivariate J-dimensional normal probabilities

$$p_i(\mathbf{C}_i \mid \mathbf{a}_i, \mathbf{b}_i) = \mathbb{P}(\mathbf{a}_i < \mathbf{Y}_i \le \mathbf{b}_i \mid \mathbf{C}_i) = (2\pi)^{-\frac{J}{2}} \det(\mathbf{C}_i)^{-\frac{1}{2}} \int_{\mathbf{a}_i}^{\mathbf{b}_i} \exp\left(-\frac{1}{2}\mathbf{y}^\top \mathbf{C}_i^{-\top} \mathbf{C}_i^{-1} \mathbf{y}\right) d\mathbf{y}$$
(1.1)

where $\mathbf{a}_i = (a_1^{(i)}, \dots, a_J^{(i)})^{\top} \in \mathbb{R}^J$ and $\mathbf{b}_i = (b_1^{(i)}, \dots, b_J^{(i)})^{\top} \in \mathbb{R}^J$ are integration limits, $\mathbf{C}_i = (c_{jj}^{(i)}) \in \mathbb{R}^{J \times J}$ is a lower triangular matrix with $c_{jj}^{(i)} = 0$ for $1 \leq j < j < J$, and thus $\mathbf{Y}_i \sim \mathbb{N}_J(\mathbf{0}_J, \mathbf{C}_i \mathbf{C}_i^{\top})$ for $i = 1, \dots, N$.

One application of these integrals is the estimation of the Cholesky factor \mathbf{C} of a J-dimensional normal distribution based on N interval-censored observations $\mathbf{Y}_1, \dots, \mathbf{Y}_J$ (encoded by \mathbf{a} and \mathbf{b}) via maximum-likelihood

$$\hat{\mathbf{C}} = \underset{\mathbf{C}}{\operatorname{argmax}} \sum_{i=1}^{N} \log(p_i(\mathbf{C} \mid \mathbf{a}_i, \mathbf{b}_i)).$$

In other applications, the Cholesky factor might also depend on i in some structured way.

Function pmvnorm in package mvtnorm computes p_i based on the covariance matrix $\mathbf{C}_i \mathbf{C}_i^{\top}$. However, the Cholesky factor \mathbf{C}_i is computed in FORTRAN. Function pmvnorm is not vectorised over $i=1,\ldots,N$ and thus separate calls to this function are necessary in order to compute likelihood contributions.

The implementation described here is a re-implementation (in R and C) of Alan Genz' original FORTRAN code, focusing on efficient computation of the log-likelihood $\sum_{i=1}^{N} \log(p_i)$ and the corresponding score function.

The document first describes a class and some useful methods for dealing with multiple lower triangular matrices $\mathbf{C}_i, i=1,\ldots,N$ in Chapter 2. The multivariate normal log-likelihood, and the corresponding score function, is implemented as outlined in Chapter 3. An example demonstrating maximum-likelihood estimation of Cholesky factors in the presence of interval-censored observations is discussed in Chapter 4. We use the technology developed here to implement the log-likelihood and score function for situations where some variables have been observed exactly and others only in form of interval-censoring in Chapter 5 and for nonparametric maximum-likelihood estimation in unstructured Gaussian copulae in Chapter 6.

```

We first define and implement infrastructure for dealing with multiple lower triangular matrices $\mathbf{C}_i \in \mathbb{R}^{J \times J}$ for i = 1, ..., N. We note that each such matrix \mathbf{C} can be stored in a vector of length J(J+1)/2. If all diagonal elements are one (that is, $c_{jj}^{(i)} \equiv 1, j = 1, ..., J$), the length of this vector is J(J-1)/2.

2.1 Multiple Lower Triangular Matrices

We can store N such matrices in an $J(J+1)/2 \times N$ matrix (diag = TRUE) or, for diag = FALSE, the $J(J-1)/2 \times N$ matrix.

Each vector might define the corresponding lower triangular matrix either in row or column-major order:

$$\mathbf{C} = \begin{pmatrix} c_{11} & & & & 0 \\ c_{21} & c_{22} & & & & \\ c_{31} & c_{32} & c_{33} & & & \\ \vdots & \vdots & & \ddots & & \\ c_{J1} & c_{J2} & \dots & c_{JJ} \end{pmatrix} \text{ matrix indexing}$$

$$= \begin{pmatrix} c_{1} & & & & 0 \\ c_{2} & c_{J+1} & & & & \\ c_{3} & c_{J+2} & c_{2J} & & & \\ \vdots & \vdots & & \ddots & & \\ c_{J} & c_{2J-1} & \dots & c_{J(J+1)/2} \end{pmatrix} \text{ column-major, byrow = FALSE}$$

$$= \begin{pmatrix} c_{1} & & & & 0 \\ c_{2} & c_{3} & & & & \\ c_{4} & c_{5} & c_{6} & & & \\ \vdots & \vdots & & \ddots & & \\ c_{J((J+1)/2-1)+1} & c_{J((J+1)/2-1)+2} & \dots & c_{J(J+1)/2} \end{pmatrix} \text{ row-major, byrow = TRUE}$$

Based on some matrix object, the dimension J is computed and checked as

 $\langle ltMatrices \ dim \ 4 \rangle \equiv$

Fragment referenced in 6a.

Typically the J dimensions are associated with names, and we therefore compute identifiers for the vector elements in either column- or row-major order on request (for later printing)

```
\langle ltMatrices names 5a \rangle \equiv
     nonames <- FALSE
      if (!isTRUE(names)) {
          if (is.character(names))
              stopifnot(is.character(names) &&
                         length(unique(names)) == J)
          else
              nonames <- TRUE
     } else {
          names <- as.character(1:J)</pre>
     if (!nonames) {
          L1 <- matrix(names, nrow = J, ncol = J)
          L2 <- matrix(names, nrow = J, ncol = J, byrow = TRUE)
          L <- matrix(paste(L1, L2, sep = "."), nrow = J, ncol = J)</pre>
          if (byrow)
              rownames(object) <- t(L)[upper.tri(L, diag = diag)]</pre>
          else
              rownames(object) <- L[lower.tri(L, diag = diag)]</pre>
     }
```

Fragment referenced in 6a.

If object is already a classed object representing lower triangular matrices (we will use the class name ltMatrices), we might want to change the storage form from row- to column-major or the other way round.

```
⟨ltMatrices input 5b⟩ ≡

if (inherits(object, "ltMatrices")) {
    ret <- .reorder(object, byrow = byrow)
    return(ret)
}</pre>
```

Fragment referenced in 6a.

The constructor essentially attaches attributes to a matrix object, possibly after some reordering / transposing

```
\langle ltMatrices 6a \rangle \equiv
      ltMatrices <- function(object, diag = FALSE, byrow = FALSE, names = TRUE) {</pre>
          if (!is.matrix(object))
               object <- matrix(object, ncol = 1L)</pre>
           ⟨ ltMatrices input 5b ⟩
           ⟨ ltMatrices dim 4 ⟩
           ⟨ ltMatrices names 5a ⟩
          attr(object, "J")
          attr(object, "diag")
                                      <- diag
          attr(object, "byrow") <- byrow</pre>
          attr(object, "rcnames") <- names</pre>
          class(object) <- c("ltMatrices", class(object))</pre>
          object
      }
      \Diamond
Fragment referenced in 2.
For the sake of completeness, we also add a constructor for symmetric multiple symmetric matrices
\langle syMatrices 6b \rangle \equiv
      as.syMatrices <- function(object) {</pre>
          stopifnot(inherits(object, "ltMatrices"))
          class(object)[1L] <- "syMatrices"</pre>
          return(object)
      }
      syMatrices <- function(object, diag = FALSE, byrow = FALSE, names = TRUE)</pre>
          as.syMatrices(ltMatrices(object = object, diag = diag, byrow = byrow, names = names))
Fragment referenced in 2.
The dimensions of such an object are always N \times J \times J and are given by
\langle dim \ ltMatrices \ 6c \rangle \equiv
      dim.ltMatrices <- function(x) {</pre>
          J <- attr(x, "J")</pre>
          return(c(attr(x, "dim")[2L], J, J)) ### ncol(unclass(x)) may trigger gc
      }
      dim.syMatrices <- dim.ltMatrices</pre>
Fragment referenced in 2.
```

The corresponding dimnames can be extracted as

```
\langle dimnames \ ltMatrices \ 7a \rangle \equiv
     dimnames.ltMatrices <- function(x)</pre>
         return(list(attr(x, "dimnames")[[2L]], attr(x, "rcnames"), attr(x, "rcnames")))
     dimnames.syMatrices <- dimnames.ltMatrices</pre>
Fragment referenced in 2.
The names identifying rows and columns in each C_i are
\langle names \ ltMatrices \ 7b \rangle \equiv
     names.ltMatrices <- function(x) {</pre>
         return(attr(x, "dimnames")[[1L]])
     names.syMatrices <- names.ltMatrices</pre>
Fragment referenced in 2.
Let's set-up an example for illustration. Throughout this document, we will compare numerical
results using
> chk <- function(...) stopifnot(isTRUE(all.equal(...)))</pre>
We start with a a simple example demonstrating how to set-up ltMatrices objects
> library("mvtnorm")
> set.seed(290875)
> N < - 4L
> J <- 5L
> rn <- paste0("C_", 1:N)
> nm <- LETTERS[1:J]</pre>
> Jn <- J * (J - 1) / 2
> ## data
> xn <- matrix(runif(N * Jn), ncol = N)
> colnames(xn) <- rn</pre>
> xd <- matrix(runif(N * (Jn + J)), ncol = N)</pre>
> colnames(xd) <- rn
> (lxn <- ltMatrices(xn, byrow = TRUE, names = nm))</pre>

2.2 Printing

For pretty printing, we coerse objects of class ltMatrices to array. The method has a logical argument called symmetric, forcing the lower triangular matrix to by interpreted as a symmetric matrix.

```
⟨ extract slots 9 ⟩ ≡

diag <- attr(x, "diag")
byrow <- attr(x, "byrow")
d <- dim(x)
J <- d[2L]
dn <- dimnames(x)
◊</pre>
Fragment referenced in 10, 11, 12, 15, 17, 19, 21a, 25.
```

```
\langle print \ ltMatrices \ 10 \rangle \equiv
      as.array.ltMatrices <- function(x, symmetric = FALSE, ...) {
          ⟨ extract slots 9 ⟩
          x <- unclass(x)
          L <- matrix(1L, nrow = J, ncol = J)
          diag(L) <- 2L
          if (byrow) {
              L[upper.tri(L, diag = diag)] \leftarrow floor(2L + 1:(J * (J - 1) / 2L + diag * J))
               L <- t(L)
          } else {
               L[lower.tri(L, diag = diag)] \leftarrow floor(2L + 1:(J * (J - 1) / 2L + diag * J))
          if (symmetric) {
              L[upper.tri(L)] <- OL
               dg <- diag(L)
              L <- L + t(L)
               diag(L) <- dg</pre>
          ret <- rbind(0, 1, x)[c(L), , drop = FALSE]
          class(ret) <- "array"</pre>
          dim(ret) \leftarrow d[3:1]
          dimnames(ret) <- dn[3:1]</pre>
          return(ret)
     }
      as.array.syMatrices <- function(x, ...)
          return(as.array.ltMatrices(x, symmetric = TRUE))
     print.ltMatrices <- function(x, ...)</pre>
          print(as.array(x))
     print.syMatrices <- function(x, ...)</pre>
          print(as.array(x))
Fragment referenced in 2.
```

Symmetric matrices are represented by lower triangular matrix objects, but we change the class from ltMatrices to syMatrices (which disables all functionality except printing and coersion to arrays).

2.3 Reordering

It is sometimes convenient to have access to lower triangular matrices in either column- or row-major order and this little helper function switches between the two forms

```
\langle reorder\ ltMatrices\ 11\ \rangle \equiv
      .reorder <- function(x, byrow = FALSE) {</pre>
          stopifnot(inherits(x, "ltMatrices"))
          if (attr(x, "byrow") == byrow) return(x)
          \langle extract \ slots \ 9 \rangle
          x <- unclass(x)
          rL \leftarrow cL \leftarrow diag(0, nrow = J)
          rL[lower.tri(rL, diag = diag)] <- cL[upper.tri(cL, diag = diag)] <- 1:nrow(x)
          cL <- t(cL)
          if (byrow) ### row -> col order
               return(ltMatrices(x[cL[lower.tri(cL, diag = diag)], , drop = FALSE],
                                   diag = diag, byrow = FALSE, names = dn[[2L]]))
          ### col -> row order
          return(ltMatrices(x[t(rL)[upper.tri(rL, diag = diag)], , drop = FALSE],
                              diag = diag, byrow = TRUE, names = dn[[2L]]))
     }
```

Fragment referenced in 2.

We can check if this works by switching back and forth between column-major and row-major order

```
> ## constructor + .reorder + as.array
> a <- as.array(ltMatrices(xn, byrow = TRUE))</pre>
> b <- as.array(ltMatrices(ltMatrices(xn, byrow = TRUE),
                            byrow = FALSE))
> chk(a, b)
> a <- as.array(ltMatrices(xn, byrow = FALSE))</pre>
> b <- as.array(ltMatrices(ltMatrices(xn, byrow = FALSE),
                            byrow = TRUE))
> chk(a, b)
> a <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE))
> b <- as.array(ltMatrices(ltMatrices(xd, byrow = TRUE, diag = TRUE),
                            byrow = FALSE))
> a <- as.array(ltMatrices(xd, byrow = FALSE, diag = TRUE))</pre>
> b <- as.array(ltMatrices(ltMatrices(xd, byrow = FALSE, diag = TRUE),
                            byrow = TRUE))
> chk(a, b)
```

2.4 Subsetting

We might want to select subsets of observations $i \in \{1, ..., N\}$ or rows/columns $j \in \{1, ..., J\}$ of the corresponding matrices \mathbf{C}_i .

```
\langle .subset \ ltMatrices \ 12 \rangle \equiv
      .subset_ltMatrices <- function(x, i, j, ..., drop = FALSE) {</pre>
          if (drop) warning("argument drop is ignored")
          if (missing(i) && missing(j)) return(x)
          \langle extract \ slots \ 9 \rangle
          x <- unclass(x)
          if (!missing(j)) {
               j <- (1:J)[j] ### get rid of negative indices</pre>
               if (length(j) == 1L && !diag) {
                   return(ltMatrices(matrix(1, ncol = ncol(x), nrow = 1), diag = TRUE,
                                        byrow = byrow, names = dn[[2L]][j]))
               L \leftarrow diag(OL, nrow = J)
               Jp <- sum(upper.tri(L, diag = diag))</pre>
               if (byrow) {
                   L[upper.tri(L, diag = diag)] <- 1:Jp</pre>
                   L \leftarrow L + t(L)
                   diag(L) \leftarrow diag(L) / 2
                   L \leftarrow L[j, j, drop = FALSE]
                   L <- L[upper.tri(L, diag = diag)]</pre>
               } else {
                   L[lower.tri(L, diag = diag)] <- 1:Jp</pre>
                   L \leftarrow L + t(L)
                   diag(L) \leftarrow diag(L) / 2
                   L \leftarrow L[j, j, drop = FALSE]
                   L <- L[lower.tri(L, diag = diag)]</pre>
               if (missing(i)) {
                   return(ltMatrices(x[c(L), , drop = FALSE], diag = diag,
                                        byrow = byrow, names = dn[[2L]][j]))
               return(ltMatrices(x[c(L), i, drop = FALSE], diag = diag,
                                   byrow = byrow, names = dn[[2L]][j]))
          }
          return(ltMatrices(x[, i, drop = FALSE], diag = diag,
                               byrow = byrow, names = dn[[2L]]))
      }
```

         ret
     }
Fragment referenced in 2.
We check if this works by first subsetting the ltMatrices object. Second, we coerse the object to
an array and do the subset for the latter object. Both results must agree.
> ## subset
> a <- as.array(ltMatrices(xn, byrow = FALSE)[1:2, 2:4])</pre>
> b <- as.array(ltMatrices(xn, byrow = FALSE))[2:4, 2:4, 1:2]
> chk(a, b)
> a <- as.array(ltMatrices(xn, byrow = TRUE)[1:2, 2:4])</pre>
> b <- as.array(ltMatrices(xn, byrow = TRUE))[2:4, 2:4, 1:2]
> a <- as.array(ltMatrices(xd, byrow = FALSE, diag = TRUE)[1:2, 2:4])
> b <- as.array(ltMatrices(xd, byrow = FALSE, diag = TRUE))[2:4, 2:4, 1:2]
> chk(a, b)
> a <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE)[1:2, 2:4])
> b <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE))[2:4, 2:4, 1:2]
> chk(a, b)
   With a different subset
> ## subset
> j < -c(1, 3, 5)
> a <- as.array(ltMatrices(xn, byrow = FALSE)[1:2, j])</pre>
> b <- as.array(ltMatrices(xn, byrow = FALSE))[j, j, 1:2]</pre>
> a <- as.array(ltMatrices(xn, byrow = TRUE)[1:2, j])</pre>
> b <- as.array(ltMatrices(xn, byrow = TRUE))[j, j, 1:2]</pre>

> b <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE))[j, j, 1:2]</pre>

> chk(a, b)

with negative subsets

```
> ## subset
> j <- -c(1, 3, 5)
> a <- as.array(ltMatrices(xn, byrow = FALSE)[1:2, j])
> b <- as.array(ltMatrices(xn, byrow = FALSE))[j, j, 1:2]
> chk(a, b)
> a <- as.array(ltMatrices(xn, byrow = TRUE)[1:2, j])
> b <- as.array(ltMatrices(xn, byrow = TRUE))[j, j, 1:2]
> chk(a, b)
> a <- as.array(ltMatrices(xd, byrow = FALSE, diag = TRUE)[1:2, j])
> b <- as.array(ltMatrices(xd, byrow = FALSE, diag = TRUE))[j, j, 1:2]
> chk(a, b)
> a <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE)[1:2, j])
> b <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE)[1:2, j])
> b <- as.array(ltMatrices(xd, byrow = TRUE, diag = TRUE))[j, j, 1:2]
> chk(a, b)
```

and with non-increasing argument j (this won't work for lower triangular matrices, only for symmetric matrices)

```
> ## subset
> j <- sample(1:J)
> ltM <- ltMatrices(xn, byrow = FALSE)
> try(ltM[1:2, j])
> ltM <- as.syMatrices(ltM)
> a <- as.array(ltM[1:2, j])
> b <- as.array(ltM)[j, j, 1:2]
> chk(a, b)
```

Extracting the lower triangular elements from an ltMatrices object (or from an object of class syMatrices) returns a matrix with N columns, undoing the effect of ltMatrices

```
\langle lower\ triangular\ elements\ 15 \rangle \equiv

```

2.6 Multiplication

Products $\mathbf{C}_i \mathbf{y}_i$ or $\mathbf{C}_i^{\top} \mathbf{y}_i$ with $\mathbf{y}_i \in \mathbb{R}^J$ for i = 1, ..., N can be computed with \mathbf{y} being an $J \times N$ matrix of columns-wise stacked vectors $(\mathbf{y}_1 \mid \mathbf{y}_2 \mid \cdots \mid \mathbf{y}_N)$. If \mathbf{y} is a single vector, it is recycled N times.

If the number of columns of a matrix y is neither one nor N, we compute $C_i y_j$ for all i = 1, ..., N and j. This is dangerous but needed in cond_mvnorm later on.

For $C_i y_i$, we call C code computing the product efficiently without copying data by leveraging the lower triangular structure of x

```
\langle mult\ ltMatrices\ 21a \rangle \equiv
      ### C %*% y
     Mult <- function(x, y, ...)</pre>
          UseMethod("Mult")
      Mult.default <- function(x, y, transpose = FALSE, ...) {</pre>
          if (!transpose) return(x %*% y)
          return(crossprod(x, y))
     Mult.ltMatrices <- function(x, y, transpose = FALSE, ...) {</pre>
          \langle extract \ slots \ 9 \rangle
          stopifnot(is.numeric(y))
          if (!is.matrix(y)) y <- matrix(y, nrow = d[2L], ncol = d[1L])</pre>
          N \leftarrow ifelse(d[1L] == 1, ncol(y), d[1L])
          stopifnot(nrow(y) == d[2L])
          if (ncol(y) != N)
               return(sapply(1:ncol(y), function(i) Mult(x, y[,i], transpose = transpose)))
          ⟨ mult ltMatrices transpose 23 ⟩
          x <- ltMatrices(x, byrow = TRUE)</pre>
          if (!is.double(x)) storage.mode(x) <- "double"</pre>
          if (!is.double(y)) storage.mode(y) <- "double"</pre>
          ret <- .Call(mvtnorm_R_ltMatrices_Mult, x, y, as.integer(N),</pre>
                         as.integer(d[2L]), as.logical(diag))
          rownames(ret) <- dn[[2L]]</pre>
          if (length(dn[[1L]]) == N)
               colnames(ret) <- dn[[1L]]</pre>
          return(ret)
     }
Fragment referenced in 2.
The underlying C code assumes C_i (here called C) to be in row-major order.
\langle RC input 21b \rangle \equiv
      /* pointer to C matrices */
     double *dC = REAL(C);
      /* number of matrices */
     int iN = INTEGER(N)[0];
      /* dimension of matrices */
     int iJ = INTEGER(J)[0];
      /* C contains diagonal elements */
     Rboolean Rdiag = asLogical(diag);
      /* p = J * (J - 1) / 2 + diag * J */
     int len = iJ * (iJ - 1) / 2 + Rdiag * iJ;
Fragment referenced in 22b, 24, 27, 28, 31a, 34, 40a.
```

We also allow C_i to be constant (N is then determined from ncol(y)). The following fragment ensures that we only loop over C_i if dim(x)[1L] > 1

```
\langle C length 22a \rangle \equiv
      int p;
      if (LENGTH(C) == len)
          /* C is constant for i = 1, ..., N */
      else
          /* C contains C_1, ...., C_N */
          p = len;
Fragment referenced in 22b, 24, 27, 28, 31a, 40a.
The C workhorse is now
\langle mult \ 22b \rangle \equiv
      SEXP R_ltMatrices_Mult (SEXP C, SEXP y, SEXP N, SEXP J, SEXP diag) {
          SEXP ans;

> b <- as.array(Tcrossprod(lxn[i,]))[,,1]</pre>
> chk(a, b, check.attributes = FALSE)
```

For $\mathbf{C}_i^{\top}\mathbf{y}_i$ (transpose = TRUE), we add a dedicated C function paying attention to the lower triangular structure of \mathbf{x} . This function assumes \mathbf{x} in column-major order, so we coerce this object when necessary:

before moving to C for the low-level computations:

```
\langle mult \ transpose \ 24 \rangle \equiv
     SEXP R_ltMatrices_Mult_transpose (SEXP C, SEXP y, SEXP N, SEXP J, SEXP diag) {
         double *dans, *dy = REAL(y);
         int i, j, k, start;
          \langle RC input 21b \rangle
          \langle C length 22a \rangle
         PROTECT(ans = allocMatrix(REALSXP, iJ, iN));
         dans = REAL(ans);
         for (i = 0; i < iN; i++) {
              start = 0;
              for (j = 0; j < iJ; j++) {
                  dans[j] = 0.0;
                  if (Rdiag) {
                      dans[j] += dC[start] * dy[j];
                      start++;
                  } else {
                      dans[j] += dy[j];
                  for (k = 0; k < (iJ - j - 1); k++)
                      dans[j] += dC[start + k] * dy[j + k + 1];
                  start += iJ - j - 1;
              }
              dC += p;
              dy += iJ;
              dans += iJ;
         UNPROTECT(1);
         return(ans);
     }
Fragment referenced in 3.
and wrap-up with some tests for computing \mathbf{C}_i^{\top} \mathbf{y}_i
> a <- Mult(lxn, y, transpose = TRUE)</pre>
> A <- as.array(lxn)</pre>
> b <- do.call("rbind", lapply(1:ncol(y),</pre>
       function(i) t(t(A[,,i]) %*% y[,i,drop = FALSE])))
> chk(a, t(b), check.attributes = FALSE)
> a <- Mult(lxd, y, transpose = TRUE)</pre>
> A <- as.array(lxd)</pre>
> b <- do.call("rbind", lapply(1:ncol(y),</pre>
       function(i) t(t(A[,,i]) \%*\% y[,i,drop = FALSE])))
> chk(a, t(b), check.attributes = FALSE)
> ### recycle C
> chk(Mult(lxn[rep(1, N),], y, transpose = TRUE),
      Mult(lxn[1,], y, transpose = TRUE), check.attributes = FALSE)
> ### recycle y
> chk(Mult(lxn, y[,1], transpose = TRUE),
```

Mult(lxn, y[,rep(1, N)], transpose = TRUE))

Now we can add a Mult method for multiple symmetric matrices, noting that for a symmetric matrix $\mathbf{C} = \mathbf{A} + \mathbf{A}^{\top} - \operatorname{diag}(\mathbf{A})$ with lower triangular part \mathbf{A} (including the diagonal) we can compute $\mathbf{C}\mathbf{y} = \mathbf{A}\mathbf{y} + \mathbf{A}^{\top}\mathbf{y} - \operatorname{diag}(\mathbf{A})\mathbf{y}$ using Mult applied to the lower trianular part:

```
\langle mult \ syMatrices \ 25 \rangle \equiv
     Mult.syMatrices <- function(x, y, ...) {</pre>
          ⟨ extract slots 9 ⟩
         class(x)[1L] <- "ltMatrices"</pre>
         stopifnot(is.numeric(y))
         if (!is.matrix(y)) y \leftarrow matrix(y, nrow = d[2L], ncol = d[1L])
         N \leftarrow ifelse(d[1L] == 1, ncol(y), d[1L])
         stopifnot(nrow(y) == d[2L])
         stopifnot(ncol(y) == N)
         ret \leftarrow Mult(x, y) + Mult(x, y, transpose = TRUE) - y * c(diagonals(x))
         return(ret)
     }
Fragment referenced in 2.
> J <- 5
> N1 <- 10
> ex <- expression({
    C \leftarrow syMatrices(matrix(runif(N2 * J * (J + c(-1, 1)[DIAG + 1L]) / 2), ncol = N2),
                       diag = DIAG)
    x \leftarrow matrix(runif(N1 * J), nrow = J)
    Ca <- as.array(C)
    p1 <- do.call("cbind", lapply(1:N1, function(i)</pre>
         Ca[,,c(1,i)[(N2 > 1) + 1]] \%*\% x[,i]))
    p2 <- Mult(C, x)</pre>
   chk(p1, p2)
+ })
> N2 <- N1
> DIAG <- TRUE
> eval(ex)
> N2 <- 1
> DIAG <- TRUE
> eval(ex)
> N2 <- 1
> DIAG <- FALSE
> eval(ex)
> N2 <- N1
> DIAG <- FALSE
> eval(ex)
```

2.7 Solving Linear Systems

Computing \mathbf{C}_i^{-1} or solving $\mathbf{C}_i\mathbf{x}_i = \mathbf{y}_i$ for \mathbf{x}_i for all i = 1, ..., N is another important task. We sometimes also need $\mathbf{C}_i^{\mathsf{T}}\mathbf{x}_i = \mathbf{y}_i$ triggered by transpose = TRUE.

C is C_i , i = 1, ..., N in column-major order (matrix of dimension $J(J-1)/2 + J \operatorname{diag} \times N$), and y

is the $J \times N$ matrix $(\mathbf{y}_1 \mid \mathbf{y}_2 \mid \cdots \mid \mathbf{y}_N)$. This function returns the $J \times N$ matrix $(\mathbf{x}_1 \mid \mathbf{x}_2 \mid \cdots \mid \mathbf{x}_N)$ of solutions.

If y is not given, \mathbf{C}_i^{-1} is returned in the same order as the original matrix \mathbf{C}_i . If all \mathbf{C}_i have unit diagonals, so will \mathbf{C}_i^{-1} .

We start with some options for the LAPACK workhorses

```
\langle lapack \ options \ 26 \rangle \equiv
     char di, lo = 'L', tr = 'N';
     if (Rdiag) {
          /* non-unit diagonal elements */
          di = 'N';
          /* unit diagonal elements; NOTE: these diagonals 1s ARE always present but
             ignored in the computations */
          di = 'U';
     }
     /* t(C) instead of C */
     Rboolean Rtranspose = asLogical(transpose);
     if (Rtranspose) {
          /* t(C) */
          tr = 'T';
     } else {
         /* C */
         tr = 'N';
     }
```

Fragment referenced in 27, 28.

and set-up a dedicated C function for computing $\mathbf{C}_i\mathbf{x}_i=\mathbf{y}_i$

```
\langle solve 27 \rangle \equiv
      SEXP R_ltMatrices_solve (SEXP C, SEXP y, SEXP N, SEXP J, SEXP diag, SEXP transpose)
          SEXP ans;
          double *dans, *dy;
          int i, j, info, ONE = 1;
          \langle RC input 21b \rangle
          /* diagonal elements are always present */
          if (!Rdiag) len += iJ;
          \langle C length 22a \rangle
          ⟨ lapack options 26 ⟩
          dy = REAL(y);
          PROTECT(ans = allocMatrix(REALSXP, iJ, iN));
          dans = REAL(ans);
          memcpy(dans, dy, iJ * iN * sizeof(double));
          /\ast loop over matrices, ie columns of C \, / y \,\ast/\,
          for (i = 0; i < iN; i++) {
               /* solve linear system */
               F77_CALL(dtpsv)(&lo, &tr, &di, &iJ, dC, dans, &ONE FCONE FCONE FCONE);
               dans += iJ;
               dC += p;
          }
          UNPROTECT(1);
          return(ans);
      }
      \Diamond
Fragment referenced in 3.
```

and then for computing C_i^{-1} explicitly

```
\langle solve C 28 \rangle \equiv
     SEXP R_ltMatrices_solve_C (SEXP C, SEXP N, SEXP J, SEXP diag, SEXP transpose)
          SEXP ans;
          double *dans;
          int i, j, info, jj, idx, ONE = 1;
          \langle RC input 21b \rangle
          /* diagonal elements are always present */
          if (!Rdiag) len += iJ;
          \langle C length 22a \rangle
          ⟨ lapack options 26 ⟩
          PROTECT(ans = allocMatrix(REALSXP, len, iN));
          dans = REAL(ans);
          memcpy(dans, dC, iN * len * sizeof(double));
          /\ast loop over matrices, ie columns of C \, / y \ast/
          for (i = 0; i < iN; i++) {
              /* compute inverse */
              F77_CALL(dtptri)(&lo, &di, &iJ, dans, &info FCONE FCONE);
              if (info != 0)
                   error("Cannot solve ltmatices");
              dans += len;
          }

2.8 Log-determinants

For computing the log-determinant $\log(\det(\mathbf{C}_i)) = \sum_{j=1}^{J} \log(\operatorname{diag}(\mathbf{C}_i)_j)$ we sum over the log-diagonal entries of a lower triangular matrix in C, both when the data are stored in row- and column-major order:

```
\langle logdet 31a \rangle \equiv
      SEXP R_ltMatrices_logdet (SEXP C, SEXP N, SEXP J, SEXP diag, SEXP byrow) {
           SEXP ans;
           double *dans;
           int i, j, k;
           \langle RC input 21b \rangle
           Rboolean Rbyrow = asLogical(byrow);
           \langle C length 22a \rangle
           PROTECT(ans = allocVector(REALSXP, iN));
           dans = REAL(ans);
           for (i = 0; i < iN; i++) {
               dans[i] = 0.0;
               if (Rdiag) {
                    k = 1;
                    for (j = 0; j < iJ; j++) {
                         dans[i] += log(dC[k - 1]);
                         k += (Rbyrow ? j + 2 : iJ - j);
                    dC += p;
               }
           }
           UNPROTECT(1);
           return(ans);
      }
      \Diamond

The R interface now simply calls this low-level function
\langle \; logdet \; ltMatrices \; 31b \, \rangle \equiv
      logdet <- function(x) {</pre>
           if (!inherits(x, "ltMatrices"))
               stop("x is not an ltMatrices object")
           byrow <- attr(x, "byrow")</pre>
           diag <- attr(x, "diag")</pre>
           d <- dim(x)
           J \leftarrow d[2L]
           dn <- dimnames(x)</pre>
           if (!is.double(x)) storage.mode(x) <- "double"</pre>
           ret <- .Call(mvtnorm_R_ltMatrices_logdet, x,</pre>
                          as.integer(d[1L]), as.integer(J), as.logical(diag),
                          as.logical(byrow))
           names(ret) <- dn[[1L]]</pre>
           return(ret)
      }
Fragment referenced in 2.
```

We test the functionality by extracting the diagonal elements from different matrices and summing over their logarithms

```
> chk(logdet(lxn), colSums(log(diagonals(lxn))))
> chk(logdet(lxd[1,]), colSums(log(diagonals(lxd[1,]))))
> chk(logdet(lxd), colSums(log(diagonals(lxd))))
> lxd2 <- ltMatrices(lxd, byrow = !attr(lxd, "byrow"))
> chk(logdet(lxd2), colSums(log(diagonals(lxd2))))
```

2.9 Crossproducts

Compute $\mathbf{C}_i \mathbf{C}_i^{\top}$ or $\operatorname{diag}(\mathbf{C}_i \mathbf{C}_i^{\top})$ (diag_only = TRUE) for $i=1,\ldots,N$. These are symmetric matrices, so we store them as a lower triangular matrix using a different class name symmetrices. We write one C function for computing $\mathbf{C}_i \mathbf{C}_i^{\top}$ or $\mathbf{C}_i^{\top} \mathbf{C}_i$ (Rtranspose being TRUE).

We differentiate between computation of the diagonal elements of the crossproduct

```
\langle first\ element\ 32a \rangle \equiv
      dans[0] = 1.0;
     if (Rdiag)
          dans[0] = pow(dC[0], 2);
     if (Rtranspose) { // crossprod
          for (k = 1; k < iJ; k++)
              dans[0] += pow(dC[IDX(k + 1, 1, iJ, Rdiag)], 2);
      }

```

2.10 Cholesky Factorisation

One might want to compute the Cholesky factorisations $\Sigma_i = \mathbf{C}_i \mathbf{C}_i^{\top}$ for multiple symmetric matrices Σ_i , stored as a matrix in class syMatrices.

```
\langle chol \ syMatrices \ 37 \rangle \equiv
      chol.syMatrices <- function(x, ...) {</pre>
          byrow_orig <- attr(x, "byrow")</pre>
          dnm <- dimnames(x)</pre>
          stopifnot(attr(x, "diag"))
          d \le dim(x)
          \#\#\# x is of class syMatrices, coerse to ltMatrices first and re-arrange
          ### second
          x <- ltMatrices(unclass(x), diag = TRUE,</pre>
                             byrow = byrow_orig, names = dnm[[2L]])
          x <- ltMatrices(x, byrow = FALSE)</pre>
          \# class(x) <- class(x)[-1]
          if (!is.double(x)) storage.mode(x) <- "double"</pre>
          ret <- .Call(mvtnorm_R_syMatrices_chol, x,</pre>
                         as.integer(d[1L]), as.integer(d[2L]))
          colnames(ret) <- dnm[[1L]]</pre>
          ret <- ltMatrices(ret, diag = TRUE,</pre>
                               byrow = FALSE, names = dnm[[2L]])
          ret <- ltMatrices(ret, byrow = byrow_orig)</pre>
          return(ret)
     }
      \Diamond
```

Luckily, we already have the data in the correct packed colum-major storage, so we swiftly loop over $i=1,\ldots,N$ in C and hand over to LAPACK

Fragment referenced in 2.

```
\langle chol 38 \rangle \equiv
     SEXP R_syMatrices_chol (SEXP Sigma, SEXP N, SEXP J) {
         SEXP ans;
         double *dans, *dSigma;
         int iJ = INTEGER(J)[0];
         int pJ = iJ * (iJ + 1) / 2;
         int iN = INTEGER(N)[0];
         int i, j, info = 0;
         char lo = 'L';
         PROTECT(ans = allocMatrix(REALSXP, pJ, iN));
         dans = REAL(ans);
         dSigma = REAL(Sigma);
         for (i = 0; i < iN; i++) {
              /* copy data */
              for (j = 0; j < pJ; j++)
                  dans[j] = dSigma[j];

                  error("argument %d of Lapack routine %s had invalid value",
                         -info, "dpptrf");
              }
              dSigma += pJ;
              dans += pJ;
         UNPROTECT(1);
         return(ans);
     }
     \Diamond
Fragment referenced in 3.
```

This new chol method can be used to revert Tcrossprod for ltMatrices with and without unit diagonals:

```
> Sigma <- Tcrossprod(lxd)
> chk(chol(Sigma), lxd)
> Sigma <- Tcrossprod(lxn)
> ## Sigma and chol(Sigma) always have diagonal, lxn doesn't
> chk(as.array(chol(Sigma)), as.array(lxn))
```

2.11 Kronecker Products

We sometimes need to compute $\text{vec}(\mathbf{S})^{\top}(\mathbf{A}^{\top} \otimes \mathbf{C})$, where \mathbf{S} is a lower triangular or other $J \times J$ matrix and \mathbf{A} and \mathbf{C} are lower triangular $J \times J$ matrices. With the "vec trick", we have $\text{vec}(\mathbf{S})^{\top}(\mathbf{A}^{\top} \otimes \mathbf{C}) = \text{vec}(\mathbf{C}^{\top}\mathbf{S}\mathbf{A}^{\top})^{\top}$. The LAPACK function dtrmm computes products of lower triangular matrices with other matrices, so we simply call this function looping over $i = 1, \dots, N$.

```
\langle t(C) S t(A) 39 \rangle \equiv
     char siR = 'R', siL = 'L', lo = 'L', tr = 'N', trT = 'T', di = 'N', trs;
     double ONE = 1.0;
     int iJ2 = iJ * iJ;
     double tmp[iJ2];
     for (j = 0; j < iJ2; j++) tmp[j] = 0.0;
     ans = PROTECT(allocMatrix(REALSXP, iJ2, iN));
     dans = REAL(ans);
     for (i = 0; i < LENGTH(ans); i++) dans[i] = 0.0;</pre>
     for (i = 0; i < iN; i++) {
         /* A := C */
         for (j = 0; j < iJ; j++) {
             for (k = 0; k \le j; k++)
                  tmp[k * iJ + j] = dC[IDX(j + 1, k + 1, iJ, 1L)];
         /* S was already expanded in R code; B = S */
         for (j = 0; j < iJ2; j++) dans[j] = dS[j];
         /* B := t(A) %*% B */
         trs = (RtC ? trT : tr);
         F77_CALL(dtrmm)(&siL, &lo, &trs, &di, &iJ, &iJ, &ONE, tmp, &iJ,
                          dans, &iJ FCONE FCONE FCONE FCONE);
         /* A */
         for (j = 0; j < iJ; j++) {
             for (k = 0; k \le j; k++)

> B <- apply(S, 2, function(x) t(Cx) %*% matrix(x, ncol = J) %*% t(Cx))
> chk(A, B)
> A <- vectrick(C, S, C, transpose = c(FALSE, FALSE))
> Cx <- as.array(C)[,,1]
> B <- apply(S, 2, function(x) Cx %*% matrix(x, ncol = J) %*% Cx)
> chk(A, B)
```

2.12 Convenience Functions

We add a few convenience functions for computing covariance matrices $\mathbf{\Sigma}_i = \mathbf{C}_i \mathbf{C}_i^{\top}$, precision matrices $\mathbf{P}_i = \mathbf{L}_i^{\top} \mathbf{L}_i$, correlation matrices $\mathbf{R}_i = \tilde{\mathbf{C}}_i \tilde{\mathbf{C}}_i^{\top}$ (where $\tilde{\mathbf{C}}_i = \operatorname{diag}(\mathbf{C}_i \mathbf{C}_i^{\top})^{-\frac{1}{2}} \mathbf{C}_i$), or matrices of partial correlations $\mathbf{A}_i = -\tilde{\mathbf{L}}_i^{\top} \tilde{\mathbf{L}}_i$ with $\tilde{\mathbf{L}}_i = \mathbf{L}_i \operatorname{diag}(\mathbf{L}_i^{\top} \mathbf{L}_i)^{-\frac{1}{2}}$ from \mathbf{L}_i (invchol) or $\mathbf{C}_i = \mathbf{L}_i^{-1}$ (chol) for $i = 1, \ldots, N$.

First, we set-up functions for computing $\tilde{\mathbf{C}}_i$

```
\langle D times C 43 \rangle \equiv Dchol <- function(x, D = 1 / sqrt(Tcrossprod(x, diag_only = TRUE))) {
```

x <- .adddiag(x)

```
byrow_orig <- attr(x, "byrow")

x <- ltMatrices(x, byrow = TRUE)

N <- dim(x)[1L]
J <- dim(x)[2L]
nm <- dimnames(x)[[2L]]

x <- unclass(x) * D[rep(1:J, 1:J),,drop = FALSE]

ret <- ltMatrices(x, diag = TRUE, byrow = TRUE, names = nm)
ret <- ltMatrices(ret, byrow = byrow_orig)
return(ret)</pre>
```

Fragment referenced in 45.

}

and
$$\tilde{\mathbf{C}}_i^{-1} = \mathbf{L}_i \operatorname{diag}(\mathbf{L}_i^{-1} \mathbf{L}_i^{-\top})^{\frac{1}{2}}$$

```
\langle\,L\ times\ D\ 44\,\rangle \equiv
      ### invcholD = solve(Dchol)
      invcholD <- function(x, D = sqrt(Tcrossprod(solve(x), diag_only = TRUE))) {</pre>
           x <- .adddiag(x)</pre>
           byrow_orig <- attr(x, "byrow")</pre>
           x <- ltMatrices(x, byrow = FALSE)</pre>
           N \leftarrow dim(x)[1L]
           J \leftarrow dim(x)[2L]
           nm <- dimnames(x)[[2L]]
           x <- unclass(x) * D[rep(1:J, J:1),,drop = FALSE]</pre>
           ret <- ltMatrices(x, diag = TRUE, byrow = FALSE, names = nm)</pre>
           ret <- ltMatrices(ret, byrow = byrow_orig)</pre>
           return(ret)
      }
      \Diamond
Fragment referenced in 45.
```

and now the convenience functions are one-liners:

```
\langle \ convenience \ functions \ 45 \ \rangle \equiv
      \langle D \ times \ C \ 43 \rangle
      \langle L \ times \ D \ 44 \rangle
      ### C -> Sigma

      check.attributes = FALSE)
   We also add an aperm method for class ltMatrices
\langle aperm 47 \rangle \equiv
     aperm.ltMatrices <- function(a, perm, is_chol = FALSE, ...) {
         if (is_chol) { ### a is Cholesky of covariance
             Sperm <- chol2cov(a)[,perm]</pre>
             return(chol(Sperm))
         }
         Sperm <- invchol2cov(a)[,perm]</pre>
         chol2invchol(chol(Sperm))
     }
Fragment referenced in 2.
> L <- 1xn
> J \leftarrow dim(L)[2L]
> Lp \leftarrow aperm(a = L, perm = p \leftarrow sample(1:J), is\_chol = FALSE)
> chk(invchol2cov(L)[,p], invchol2cov(Lp))
> C <- 1xn
> J <- dim(C)[2L]
> Cp <- aperm(a = C, perm = p <- sample(1:J), is_chol = TRUE)
> chk(chol2cov(C)[,p], chol2cov(Cp))
```

2.13 Marginal and Conditional Normal Distributions

Marginal and conditional distributions from distributions $\mathbf{Y}_i \sim \mathbb{N}_J(\mathbf{0}_J, \mathbf{C}_i \mathbf{C}_i^\top)$ (chol argument for \mathbf{C}_i for $i = 1, \dots, N$) or $\mathbf{Y}_i \sim \mathbb{N}_J(\mathbf{0}_J, \mathbf{L}_i^{-1} \mathbf{L}_i^{-\top})$ (invchol argument for \mathbf{L}_i for $i = 1, \dots, N$) shall be computed.

```
⟨ mc input checks 48a⟩ ≡

stopifnot(xor(missing(chol), missing(invchol)))
x <- if (missing(chol)) invchol else chol

stopifnot(inherits(x, "ltMatrices"))

N <- dim(x)[1L]
J <- dim(x)[2L]
if (is.character(which)) which <- match(which, dimnames(x)[[2L]])
stopifnot(all(which %in% 1:J))

◊</pre>
```

Fragment referenced in 48b, 50b.

The first j marginal distributions can be obtained from subsetting \mathbf{C} or \mathbf{L} directly. Arbitrary marginal distributions are based on the corresponding subset of the covariance matrix for which we compute a corresponding Cholesky factor (such that we can use lpmvnorm later on).

```
\langle marginal 48b \rangle \equiv
      marg_mvnorm <- function(chol, invchol, which = 1L) {</pre>
           \langle mc \ input \ checks \ 48a \rangle
           if (which[1] == 1L && (length(which) == 1L ||
                                        all(diff(which) == 1L))) {
                ### which is 1:j
                tmp <- x[,which]</pre>
           } else {
                if (missing(chol)) x <- solve(x)</pre>
                tmp <- base::chol(Tcrossprod(x)[,which])</pre>
                if (missing(chol)) tmp <- solve(tmp)</pre>
           if (missing(chol))
                ret <- list(invchol = tmp)</pre>
                ret <- list(chol = tmp)</pre>
           ret
      }
```

Fragment referenced in 2.

We compute conditional distributions from the precision matrices $\Sigma_i^{-1} = \mathbf{P}_i = \mathbf{L}_i^{\top} \mathbf{L}_i$ (we omit the *i* index from now on). For an arbitrary subset $\mathbf{j} \subset \{1, \dots, J\}$, the conditional distribution of $\mathbf{Y}_{-\mathbf{j}}$ given $\mathbf{Y}_{\mathbf{j}} = \mathbf{y}_{\mathbf{j}}$ is

$$\mathbf{Y_{-j}} \mid \mathbf{Y_j} = \mathbf{y_j} \sim \mathbb{N}_{|\mathbf{j}|} \left(-\mathbf{P_{-j,-j}^{-1}} \mathbf{P_{-j,j}} \mathbf{y_j}, \mathbf{P_{-j,-j}^{-1}} \right)$$

and we return a Cholesky factor $\tilde{\mathbf{C}}$ such that $\mathbf{P}_{-\mathbf{j},-\mathbf{j}}^{-1} = \tilde{\mathbf{C}}\tilde{\mathbf{C}}^{\top}$ (if chol was given) or $\tilde{\mathbf{L}} = \tilde{\mathbf{C}}^{-1}$ (if invchol was given).

We can implement this as

```
\langle cond \ general \ 49 \rangle \equiv
     stopifnot(!center)
     if (!missing(chol)) ### chol is C = Cholesky of covariance
          P \leftarrow Crossprod(solve(chol)) ### P = t(L) %*% L with L = C^-1
                           ### invcol is L = Cholesky of precision
          P <- Crossprod(invchol)
     Pw <- P[, -which]
     chol <- solve(base::chol(Pw))</pre>
     Pa <- as.array(P)
     Sa <- as.array(S <- Crossprod(chol))
     if (dim(chol)[1L] == 1L) {
         Pa <- Pa[,,1]
         Sa <- Sa[,,1]
        mean <- -Sa %*% Pa[-which, which, drop = FALSE] %*% given
     } else {
         if (ncol(given) == N) {
             mean <- sapply(1:N, function(i)</pre>
                 -Sa[,,i] %*% Pa[-which,which,i] %*% given[,i,drop = FALSE])
         } else {    ### compare to Mult() with ncol(y) !%in% (1, N)
             mean <- sapply(1:N, function(i)</pre>
                 -Sa[,,i] %*% Pa[-which,which,i] %*% given)
         }
     }
```

Fragment referenced in 50b.

If $\mathbf{j} = \{1, \dots, j < J\}$ and \mathbf{L} is given, computations simplify a lot because the conditional precision matrix is

$$\mathbf{P}_{-\mathbf{j},-\mathbf{j}} = (\mathbf{L}^{\top}\mathbf{L})_{-\mathbf{j},-\mathbf{j}} = \mathbf{L}_{-\mathbf{i},-\mathbf{i}}^{\top}\mathbf{L}_{-\mathbf{j},-\mathbf{j}}$$

and thus we return $\tilde{\mathbf{L}} = \mathbf{L}_{-\mathbf{j},-\mathbf{j}}$ (if invchol was given) or $\tilde{\mathbf{C}} = \mathbf{L}_{-\mathbf{j},-\mathbf{j}}^{-1}$ (if chol was given). The conditional mean is

$$\begin{array}{lcl} -\mathbf{P}_{-\mathbf{j},-\mathbf{j}}^{-1}\mathbf{P}_{-\mathbf{j},\mathbf{j}}\mathbf{y}_{\mathbf{j}} & = & -\mathbf{L}_{-\mathbf{j},-\mathbf{j}}^{-1}\mathbf{L}_{-\mathbf{j},-\mathbf{j}}^{-\top}\mathbf{L}_{-\mathbf{j},-\mathbf{j}}^{\top}\mathbf{L}_{-\mathbf{j},\mathbf{j}}\mathbf{y}_{\mathbf{j}} \\ & = & -\mathbf{L}_{-\mathbf{j},-\mathbf{j}}^{-1}\mathbf{L}_{-\mathbf{j},\mathbf{j}}\mathbf{y}_{\mathbf{j}}. \end{array}$$

We sometimes, for example when scores with respect to $\mathbf{L}_{-\mathbf{j},-\mathbf{j}}^{-1}$ shall be computed in slpmvnorm, need the negative rescaled mean $\mathbf{L}_{-\mathbf{j},\mathbf{j}}\mathbf{y}_{\mathbf{j}}$ and the center = TRUE argument triggers this values to be returned.

The implementation reads

```
\langle cond simple 50a \rangle \equiv
     if (which[1] == 1L && (length(which) == 1L ||
                               all(diff(which) == 1L))) {
          ### which is 1:j
          L <- if (missing(invchol)) solve(chol) else invchol
          tmp <- matrix(0, ncol = ncol(given), nrow = J - length(which))</pre>
          centerm <- Mult(L, rbind(given, tmp))[-which,,drop = FALSE]</pre>
          L <- L[,-which]</pre>
          if (missing(invchol)) {
              if (center)
                  return(list(center = centerm, chol = solve(L)))
              return(list(mean = -solve(L, centerm), chol = solve(L)))
          }
          if (center)
              return(list(center = centerm, invchol = L))
          return(list(mean = -solve(L, centerm), invchol = L))
     }
Fragment referenced in 50b.
\langle conditional 50b \rangle \equiv
     cond_mvnorm <- function(chol, invchol, which_given = 1L, given, center = FALSE) {</pre>
          which <- which_given
          \langle mc \ input \ checks \ 48a \rangle

Let's check this against the commonly used formula based on the covariance matrix, first for the
marginal distribution
> Sigma <- Tcrossprod(lxd)</pre>
> j <- 1:3
> chk(Sigma[,j], Tcrossprod(marg_mvnorm(chol = lxd, which = j)$chol))
> j <- 2:4
> chk(Sigma[,j], Tcrossprod(marg_mvnorm(chol = lxd, which = j)$chol))
> Sigma <- Tcrossprod(solve(lxd))</pre>
> chk(Sigma[,j], Tcrossprod(solve(marg_mvnorm(invchol = lxd, which = j)$invchol)))
```

```
> j <- 2:4
> chk(Sigma[,j], Tcrossprod(solve(marg_mvnorm(invchol = lxd, which = j)$invchol)))
   and then for conditional distributions. The general case is
> Sigma <- as.array(Tcrossprod(lxd))[,,1]</pre>
> j <- 2:4

```

2.14 Continuous Log-likelihoods

With $\mathbf{Z} \sim \mathbb{N}_J(0, \mathbf{I}_J)$ and $\mathbf{Y} = \mathbf{C}_i \mathbf{Z} + \boldsymbol{\mu}_i \sim \mathbb{N}_J(\boldsymbol{\mu}_i, \mathbf{C}_i \mathbf{C}_i^{\top})$ we want to evaluate the log-likelihood contributions for observations $\mathbf{y}_1, \dots, \mathbf{y}_N$ in a function called ldmvnorm

```
\langle ldmvnorm 52a \rangle \equiv
      ldmvnorm <- function(obs, mean = 0, chol, invchol, logLik = TRUE) {</pre>
          stopifnot(xor(missing(chol), missing(invchol)))
          if (!is.matrix(obs)) obs <- matrix(obs, ncol = 1L)</pre>
          p <- ncol(obs)
          if (!missing(chol)) {
                 \langle ldmvnorm \ chol \ 54a \rangle
          } else {
                 ⟨ ldmvnorm invchol 54b ⟩
          names(logretval) <- colnames(obs)</pre>
          if (logLik) return(sum(logretval))
          return(logretval)
      }
Fragment referenced in 2.
We first check if the observations \mathbf{y}_1, \dots, \mathbf{y}_N are given in an J \times N matrix obs with corresponding
means \mu_1, \ldots, \mu_N in means.
\langle check \ obs \ 52b \rangle \equiv
      .check_obs <- function(obs, mean, J, N) {</pre>
          nr <- nrow(obs)</pre>
          nc <- ncol(obs)</pre>
          if (nc != N)
               stop("obs and (inv)chol have non-conforming size")
               stop("obs and (inv)chol have non-conforming size")
          if (identical(unique(mean), 0)) return(obs)
          if (length(mean) == J)
               return(obs - c(mean))
          if (!is.matrix(mean))
               stop("obs and mean have non-conforming size")
          if (nrow(mean) != nr)
               stop("obs and mean have non-conforming size")
```

Fragment referenced in 2.

}

With $\Sigma_i = \mathbf{C}_i \mathbf{C}_i^{\top}$ the log-likelihood function for $\mathbf{Y}_i = \mathbf{y}_i$ is

stop("obs and mean have non-conforming size")

if (ncol(mean) != nc)

return(obs - mean)

$$\ell_i(\boldsymbol{\mu}_i, \mathbf{C}_i) = -\frac{k}{2}\log(2\pi) - \frac{1}{2}\log|\boldsymbol{\Sigma}_i| - \frac{1}{2}(\mathbf{y}_i - \boldsymbol{\mu}_i)^{\top}\boldsymbol{\Sigma}_i^{-1}(\mathbf{y}_i - \boldsymbol{\mu}_i)$$

Because $\log |\Sigma_i| = \log |C_iC_i^\top| = 2\log |C_i| = 2\sum_{j=1}^{J} \log \operatorname{diag}(C_i)_j$ we get the simpler expression

$$\ell_i(\boldsymbol{\mu}_i, \mathbf{C}_i) = -\frac{k}{2} \log(2\pi) - \sum_{j=1}^{J} \log \operatorname{diag}(\mathbf{C}_i)_j - \frac{1}{2} (\mathbf{y}_i - \boldsymbol{\mu}_i)^{\top} \mathbf{C}_i^{-\top} \mathbf{C}_i^{-1} (\mathbf{y} - \boldsymbol{\mu}_i).$$
 (2.1)

We need to compute colSums(dnorm(z, log = TRUE)) quite often. This turns out to be time-consuming and memory intensive, so we provide a small internal helper function focusing on the necessary computations.

```
\langle colSumsdnorm 53a \rangle \equiv
      SEXP R_ltMatrices_colSumsdnorm (SEXP z, SEXP N, SEXP J) {
          /* number of columns */
          int iN = INTEGER(N)[0];
          /* number of rows */
          int iJ = INTEGER(J)[0];
          SEXP ans;
          double *dans, Jl2pi, *dz;
          J12pi = iJ * log(2 * PI);
          PROTECT(ans = allocVector(REALSXP, iN));
          dans = REAL(ans);
          dz = REAL(z);
          for (int i = 0; i < iN; i++) {
              dans[i] = 0.0;
              for (int j = 0; j < iJ; j++)
                   dans[i] += pow(dz[j], 2);
              dans[i] = -0.5 * (Jl2pi + dans[i]);
               dz += iJ;
          }
          UNPROTECT(1);
          return(ans);
      }
Fragment referenced in 3.
\langle colSumsdnorm\ ltMatrices\ 53b \rangle \equiv
      .colSumsdnorm <- function(z) {</pre>
          stopifnot(is.numeric(z))
          if (!is.matrix(z))
              z <- matrix(z, nrow = 1, ncol = length(z))</pre>
          ret <- .Call(mvtnorm_R_ltMatrices_colSumsdnorm, z, ncol(z), nrow(z))</pre>
          names(ret) <- colnames(z)</pre>
          return(ret)
     }
     \Diamond
```

The main part is now

where we can use the efficient implementations of solve and logdet.

If $\mathbf{L}_i = \mathbf{C}_i^{-1}$ is given, we obtain

$$\ell_i(\boldsymbol{\mu}_i, \mathbf{L}_i) = -\frac{k}{2} \log(2\pi) + \sum_{j=1}^{J} \log \operatorname{diag}(\mathbf{L}_i)_j - \frac{1}{2} (\mathbf{y}_i - \boldsymbol{\mu}_i)^{\top} \mathbf{L}_i^{\top} \mathbf{L}_i (\mathbf{y} - \boldsymbol{\mu}_i).$$

 $\langle ldmvnorm invchol 54b \rangle \equiv$

```
## invchol is given
if (!inherits(invchol, "ltMatrices"))
    stop("invchol is not an object of class ltMatrices")
N <- dim(invchol)[1L]
N <- ifelse(N == 1, p, N)
J <- dim(invchol)[2L]
obs <- .check_obs(obs = obs, mean = mean, J = J, N = N)
## NOTE: obs is (J x N)
## dnorm takes rather long
z <- Mult(invchol, obs)
logretval <- .colSumsdnorm(z)
## note that the second summand gets recycled the correct number
## of times in case dim(invchol)[1L] == 1 but ncol(obs) > 1
if (attr(invchol, "diag"))
    logretval <- logretval + logdet(invchol)</pre>
```

Fragment referenced in 52a.

The score function with respect to obs is

$$\frac{\partial \ell_i(\boldsymbol{\mu}_i, \mathbf{L}_i)}{\partial \mathbf{y}_i} = -\mathbf{L}_i^{\top} \mathbf{L}_i \mathbf{y}_i$$

and with respect to invchol we have

$$\frac{\partial \ell_i(\boldsymbol{\mu}_i, \mathbf{L}_i)}{\partial \mathbf{L}_i} = -2\mathbf{L}_i \mathbf{y}_i \mathbf{y}_i^\top + \mathrm{diag}(\mathbf{L}_i)^{-1}.$$

The score function with respect to chol post-processes the above score using the vec trick (Section 2.11). For the log-likelihood (2.1), the score with respect to \mathbf{C}_i is the sum of the score functions of the two terms. We start with the simpler first term

$$\frac{\partial - \sum_{j=1}^{J} \log \operatorname{diag}(\mathbf{C}_{i})_{j}}{\partial \mathbf{C}_{i}} = -\operatorname{diag}(\mathbf{C}_{i})^{-1}$$

The second term gives (we omit the mean for the sake of simplicity)

$$\frac{\partial -\mathbf{y}_{i}^{\top} \mathbf{C}_{i}^{-\top} \mathbf{C}_{i}^{-1} \mathbf{y}_{i}}{\partial \mathbf{C}_{i}} = -\frac{\partial \mathbf{y}_{i}^{\top} \mathbf{A}^{\top} \mathbf{A} \mathbf{y}_{i}}{\partial \mathbf{A}} \Big|_{\mathbf{A} = \mathbf{C}_{i}^{-1}} \frac{\partial \mathbf{A}^{-1}}{\partial \mathbf{A}} \Big|_{\mathbf{A} = \mathbf{C}_{i}}$$

$$= -2 \text{vec}(\mathbf{C}_{i}^{-1} \mathbf{y}_{i} \mathbf{y}_{i}^{\top})^{\top} (-1)(\mathbf{C}_{i}^{-\top} \otimes \mathbf{C}_{i}^{-1})$$

$$= 2 \text{vec}(\mathbf{C}_{i}^{-\top} \mathbf{C}_{i}^{-1} \mathbf{y}_{i} \mathbf{y}_{i}^{\top} \mathbf{C}_{i}^{-\top})^{\top}$$

In sldmvnorm, we compute the score with respect to \mathbf{L}_i and use the above relationship to compute the score with respect to \mathbf{C}_i .

```
\langle sldmvnorm 56 \rangle \equiv
     sldmvnorm <- function(obs, mean = 0, chol, invchol, logLik = TRUE) {</pre>
          stopifnot(xor(missing(chol), missing(invchol)))
          if (!is.matrix(obs)) obs <- matrix(obs, ncol = 1L)</pre>
          if (!missing(invchol)) {
              N <- dim(invchol)[1L]
              N <- ifelse(N == 1, ncol(obs), N)
              J <- dim(invchol)[2L]</pre>
              obs <- .check_obs(obs = obs, mean = mean, J = J, N = N)
              Mix <- Mult(invchol, obs)</pre>
              sobs <- - Mult(invchol, Mix, transpose = TRUE)</pre>
              Y \leftarrow matrix(obs, byrow = TRUE, nrow = J, ncol = N * J)
              ret <- - matrix(Mix[, rep(1:N, each = J)] * Y, ncol = N)</pre>
              M \leftarrow matrix(1:(J^2), nrow = J, byrow = FALSE)
              ret <- ltMatrices(ret[M[lower.tri(M, diag = attr(invchol, "diag"))],,drop = FALSE],</pre>
                                  diag = attr(invchol, "diag"), byrow = FALSE)
              ret <- ltMatrices(ret,</pre>
                                  diag = attr(invchol, "diag"), byrow = attr(invchol, "byrow"))
              if (attr(invchol, "diag")) {
                  ### recycle properly
                  diagonals(ret) <- diagonals(ret) + c(1 / diagonals(invchol))</pre>
              } else {
                  diagonals(ret) <- 0
              ret <- list(obs = sobs, invchol = ret)</pre>
              if (logLik)
                  ret$logLik <- ldmvnorm(obs = obs, mean = mean, invchol = invchol, logLik = FALSE)
              return(ret)
          }
          invchol <- solve(chol)</pre>
          ret <- sldmvnorm(obs = obs, mean = mean, invchol = invchol)</pre>
          ### this means: ret$chol <- - vectrick(invchol, ret$invchol, invchol)</pre>
          ret$chol <- - vectrick(invchol, ret$invchol)</pre>
          ret$invchol <- NULL
          return(ret)
     }
```

2.15 Application Example

Let's say we have $\mathbf{Y}_i \sim \mathbb{N}_J(\mathbf{0}_J, \mathbf{C}_i \mathbf{C}_i^{\top})$ for i = 1, ..., N and we know the Cholesky factors $\mathbf{L}_i = \mathbf{C}_i^{-1}$ of the N precision matrices $\Sigma^{-1} = \mathbf{L}_i \mathbf{L}_i^{\top}$. We generate $\mathbf{Y}_i = \mathbf{L}_i^{-1} \mathbf{Z}_i$ from $\mathbf{Z}_i \sim \mathbb{N}_J(\mathbf{0}_J, \mathbf{I}_J)$. Evaluating the corresponding log-likelihood is now straightforward and fast, compared to repeated calls to dmvnorm

```
> N <- 1000L
> J <- 50L
```

The ldmvnorm function now also has chol and invchol arguments such that we can use

```
> 113 <- ldmvnorm(obs = Y, invchol = lt)
> chk(111, 113)
```

Note that argument obs in ldmvnorm is an $J \times N$ matrix whereas the traditional interface in dmvnorm expects an $N \times J$ matrix x. The reason is that Mult or solve work with $J \times N$ matrices and we want to avoid matrix transposes.

Sometimes it is preferable to split the joint distribution into a marginal distribution of some elements and the conditional distribution given these elements. The joint density is, of course, the product of the marginal and conditional densities and we can check if this works for our example by

Chapter 3

Multivariate Normal Log-likelihoods

We now discuss code for evaluating the log-likelihood

$$\sum_{i=1}^{N} \log(p_i(\mathbf{C}_i \mid \mathbf{a}_i, \mathbf{b}_i))$$

This is relatively simple to achieve using the existing pmvnorm function, so a prototype might look like

```
\langle lpmvnormR 58 \rangle \equiv
      lpmvnormR <- function(lower, upper, mean = 0, center = NULL, chol, logLik = TRUE, ...) {</pre>
          ⟨ input checks 60a ⟩
          sigma <- Tcrossprod(chol)</pre>
          S <- as.array(sigma)</pre>
          idx <- 1
          ret <- error <- numeric(N)</pre>
          for (i in 1:N) {
               if (dim(sigma)[[1L]] > 1) idx <- i</pre>
               tmp <- pmvnorm(lower = lower[,i], upper = upper[,i], sigma = S[,,idx], ...)</pre>
               ret[i] <- tmp
               error[i] <- attr(tmp, "error")</pre>
          attr(ret, "error") <- error
          if (logLik)
               return(sum(log(pmax(ret, .Machine$double.eps))))
          ret
     }
```

Fragment never referenced.

However, the underlying FORTRAN code first computes the Cholesky factor based on the covariance matrix, which is clearly a waste of time. Repeated calls to FORTRAN also cost some time. The code (based on and evaluated in Genz and Bretz, 2002) implements a specific form of quasi-Monte-Carlo integration without allowing the user to change the scheme (or to fall-back to simple Monte-Carlo). We therefore implement our own simplified version, with the aim to speed-things up such that maximum-likelihood estimation becomes a bit faster.

Let's look at an example first. This code estimates p_1, \ldots, p_{10} for a 5-dimensional normal

```
> J <- 5L
> N <- 10L
> x <- matrix(runif(N * J * (J + 1) / 2), ncol = N)
> lx <- ltMatrices(x, byrow = TRUE, diag = TRUE)
> a <- matrix(runif(N * J), nrow = J) - 2
> a[sample(J * N)[1:2]] <- -Inf
> b <- a + 2 + matrix(runif(N * J), nrow = J)
> b[sample(J * N)[1:2]] <- Inf
> (phat <- c(lpmvnormR(a, b, chol = lx, logLik = FALSE)))

[1] 0.2369329 0.2337179 0.2842052 0.3915213 0.4662496 0.0000000 0.5900784
[8] 0.4618524 0.4872819 0.0000000</pre>
```

We want to achieve the same result a bit more general and a bit faster, by making the code more modular and, most importantly, by providing score functions for all arguments \mathbf{a}_i , \mathbf{b}_i , and \mathbf{C}_i .

3.1 Algorithm

```
"lpmvnorm.R" 59a \equiv
       \langle R \; Header \; 104 \rangle
       \langle lpmvnorm 69 \rangle
       \langle slpmvnorm 82 \rangle
"lpmvnorm.c" 59b \equiv
       \langle C Header 105 \rangle
       #ifndef USE_FC_LEN_T
       # define USE_FC_LEN_T
       #endif
       #include <Rconfig.h>
       #include <R_ext/BLAS.h> /* for dtrmm */
       #ifndef FCONE
       # define FCONE
       #endif
       #include <R.h>
       #include <Rmath.h>
       #include <Rinternals.h>
       #include <Rdefines.h>
       ⟨ pnorm fast 64a ⟩
       ⟨ pnorm slow 64b ⟩
       \langle R \ lpmvnorm \ 67 \rangle
       \langle R \ slpmvnorm \ 79 \rangle
       \Diamond
```

We implement the algorithm described by Genz (1992). The key point here is that the original J-dimensional problem (1.1) is transformed into an integral over $[0,1]^{J-1}$.

```
For each i = 1, ..., N, do
```

```
1. Input C_i (chol), a_i (lower), b_i (upper), and control parameters \alpha, \epsilon, and M_{\text{max}} (M).

Next we generate some data and compare our implementation to pmvnorm using quasi-Monte-Carlo integration. The pmvnorm function uses randomised Korobov rules. The experiment here applies generalised Halton sequences. Plain Monte-Carlo ($\mathbf{w} = \mathtt{NULL}$) will also work but produces more variable results. Results will depend a lot on appropriate choices and it is the users responsibility to make sure things work as intended. If you are unsure, you should use pmvnorm which provides a well-tested configuration.

```

Because the default fast = FALSE was used here, all results are identical.

3.2 Score Function

In addition to the log-likelihood, we would also like to have access to the scores with respect to C_i . Because every element of C_i only enters once, the chain rule rules, so to speak.

We need the derivatives of d, e, y, and f with respect to the c parameters

and we start allocating the necessary memory. The output object contains the likelihood contributions (first row), the scores with respect to the mean (next J rows), with respect to the lower integration limits (next J rows), with respect to the upper integration limits (next J rows) and finally with respect to the off-diagonal elements of the Cholesky factor (last J(J-1)/2 rows).

```
\langle score\ output\ object\ 72a \rangle \equiv
      int Jp = iJ * (iJ + 1) / 2;
      ⟨ chol scores 71a ⟩
      ⟨ mean scores 71b ⟩
      ⟨ lower scores 71c ⟩
      ⟨ upper scores 71d ⟩
      double dtmp, etmp, Wtmp, ytmp, xx;
      PROTECT(ans = allocMatrix(REALSXP, Jp + 1 + 3 * iJ, iN));
      dans = REAL(ans);
      for (j = 0; j < LENGTH(ans); j++) dans[j] = 0.0;
Fragment referenced in 79.
For each i = 1, \ldots, N, do
   1. Input C_i (chol), a_i (lower), b_i (upper), and control parameters \alpha, \epsilon, and M_{\text{max}} (M).
  2. Standardise integration limits a_j^{(i)}/c_{jj}^{(i)}, b_j^{(i)}/c_{jj}^{(i)}, and rows c_{jj}^{(i)}/c_{jj}^{(i)} for 1 \leq j < j < J.
      Note: We later need derivatives wrt c_{ij}^{(i)}, so we compute derivates wrt a_i^{(i)} and b_i^{(i)} and
      post-differentiate later.
  3. Initialise intsum = varsum = 0, M = 0, d_1 = \Phi\left(a_1^{(i)}\right), e_1 = \Phi\left(b_1^{(i)}\right) and f_1 = e_1 - d_1.
      We start initialised the score wrt to c_{11}^{(i)} (the parameter is non-existent here due to standard-
      isation)
      \langle score \ c11 \ 72b \rangle \equiv

The R code is now essentially identical to lpmvnorm, however, we need to undo the effect of standardisation once the scores have been computed

```
\langle post \ differentiate \ mean \ score \ 80a \rangle \equiv
       Jp <- J * (J + 1) / 2;
       smean <- - ret[Jp + 1:J, , drop = FALSE]</pre>
      if (attr(chol, "diag"))
            smean <- smean / c(dchol)</pre>
Fragment referenced in 82.
\langle post \ differentiate \ lower \ score \ 80b \rangle \equiv
       slower <- ret[Jp + J + 1:J, , drop = FALSE]</pre>
      if (attr(chol, "diag"))
            slower <- slower / c(dchol)</pre>
Fragment referenced in 82.
\langle post \ differentiate \ upper \ score \ 80c \rangle \equiv
       supper <- ret[Jp + 2 * J + 1:J, , drop = FALSE]</pre>
       if (attr(chol, "diag"))
            supper <- supper / c(dchol)</pre>
Fragment referenced in 82.
\langle \; post \; differentiate \; chol \; score \; 80d \, \rangle \equiv
      if (J == 1) {
            idx <- 1L
      } else {
            idx <- cumsum(c(1, 2:J))
      if (attr(chol, "diag")) {
            ret <- ret / c(dchol[rep(1:J, 1:J),]) ### because 1 / dchol already there
            ret[idx,] <- -ret[idx,]</pre>
      }
      \Diamond
```

We sometimes parameterise models in terms of $\mathbf{L} = \mathbf{C}^{-1}$, the Cholesky factor of the precision matrix. The log-likelihood operates on \mathbf{C} , so we need to post-differentiate the score function. We have

$$\mathbf{A} = \frac{\partial \mathbf{L}^{-1}}{\partial \mathbf{L}} = -\mathbf{L}^{-\top} \otimes \mathbf{L}^{-1}$$

Fragment referenced in 82.

and computing $\mathbf{s}\mathbf{A}$ for a score vector \mathbf{s} with respect to \mathbf{L} can be implemented by the "vec trick" (Section 2.11)

$$\mathbf{s}\mathbf{A} = \mathbf{L}^{-\top}\mathbf{S}\mathbf{L}^{-\top}$$

```
where \mathbf{s} = \mathrm{vec}(\mathbf{S}). 
 \langle \textit{post differentiate invchol score 81a} \rangle \equiv 
 if (!missing(invchol)) { 
    ret <- ltMatrices(ret, diag = TRUE, byrow = TRUE) 
    ### this means vectrick(chol, ret, chol) 
    ret <- - unclass(vectrick(chol, ret)) 
 } 
 \diamond 
 Fragment referenced in 82.
```

If the diagonal elements are constants, we set them to zero. The function always returns an object of class ltMatrices with explicit diagonal elements (use Lower_tri(, diag = FALSE) to extract the lower triangular elements such that the scores match the input)

```
⟨ post process score 81b ⟩ ≡

if (!attr(chol, "diag"))
    ### remove scores for constant diagonal elements
    ret[idx,] <- 0
    ret <- ltMatrices(ret, diag = TRUE, byrow = TRUE)
    ◊

Fragment referenced in 82.</pre>
```

We can now finally put everything together in a single score function.

```
\langle slpmvnorm 82 \rangle \equiv

          }
          return(ret)
      }
Fragment referenced in 59a.
Let's look at an example, where we use numDeriv::grad to check the results
> J <- 5L
> N <- 4L
> S <- crossprod(matrix(runif(J^2), nrow = J))
> prm <- t(chol(S))[lower.tri(S, diag = TRUE)]
> ### define C
> mC <- ltMatrices(matrix(prm, ncol = 1), diag = TRUE)
> a <- matrix(runif(N * J), nrow = J) - 2
> b <- a + 4
```

```
> a[2,] <- -Inf
> b[3,] <- Inf
> M <- 10000L
> W \leftarrow matrix(runif(M * (J - 1)), ncol = M)
> lli <- c(lpmvnorm(a, b, chol = mC, w = W, M = M, logLik = FALSE))
> fC <- function(prm) {</pre>
      C <- ltMatrices(matrix(prm, ncol = 1), diag = TRUE)</pre>
      lpmvnorm(a, b, chol = C, w = W, M = M)
+ }
> sC \leftarrow slpmvnorm(a, b, chol = mC, w = W, M = M)
> chk(lli, sC$logLik)
> if (require("numDeriv", quietly = TRUE))
      chk(grad(fC, unclass(mC)), rowSums(unclass(sC$chol)), check.attributes = FALSE)
   We can do the same when L (and not C) is given
> mL <- solve(mC)
> lliL <- c(lpmvnorm(a, b, invchol = mL, w = W, M = M, logLik = FALSE))
> chk(lli, lliL)
> fL <- function(prm) {</pre>
      L <- ltMatrices(matrix(prm, ncol = 1), diag = TRUE)
      lpmvnorm(a, b, invchol = L, w = W, M = M)
+ }
> sL <- slpmvnorm(a, b, invchol = mL, w = W, M = M)
> chk(lliL, sL$logLik)
> if (require("numDeriv", quietly = TRUE))
      chk(grad(fL, unclass(mL)), rowSums(unclass(sL$invchol)),
          check.attributes = FALSE)
  The score function also works for univariate problems

Chapter 4

Maximum-likelihood Example

We now discuss how this infrastructure can be used to estimate the Cholesky factor of a multivariate normal in the presence of interval-censored observations.

We first generate a covariance matrix $\Sigma = \mathbf{C}\mathbf{C}^{\top}$ and extract the Cholesky factor \mathbf{C}

```
> J <- 4
> R \leftarrow diag(J)
> R[1,2] <- R[2,1] <- .25
> R[1,3] <- R[3,1] <- .5
> R[2,4] <- R[4,2] <- .75
> ### ATLAS and M1mac print 0 as something < .Machine$double.eps
> round(Sigma <- diag(sqrt(1:J / 2)) %*% R %*% diag(sqrt(1:J / 2)), 7)</pre>
          [,1]
                     [,2]
                               [,3]
[1,] 0.5000000 0.1767767 0.4330127 0.00000
[2,] 0.1767767 1.0000000 0.0000000 1.06066
[3,] 0.4330127 0.0000000 1.5000000 0.00000
[4,] 0.0000000 1.0606602 0.0000000 2.00000
> (C <- t(chol(Sigma)))</pre>
          [,1]
                      [,2]
                                [,3]
[1,] 0.7071068 0.0000000 0.0000000 0.0000000
[2,] 0.2500000 0.9682458 0.0000000 0.0000000
[3,] 0.6123724 -0.1581139 1.0488088 0.0000000
[4,] 0.0000000 1.0954451 0.1651446 0.8790491
   We now represent this matrix as ltMatrices object
> prm <- C[lower.tri(C, diag = TRUE)]</pre>
> lt <- ltMatrices(matrix(prm, ncol = 1L),
                   diag = TRUE,
                                    ### has diagonal elements
                   byrow = FALSE)
                                    ### prm is column-major
> BYROW <- FALSE
                   ### later checks
> lt <- ltMatrices(lt,
                   byrow = BYROW)
                                     ### convert to row-major
> chk(C, as.array(lt)[,,1], check.attributes = FALSE)
> chk(Sigma, as.array(Tcrossprod(lt))[,,1], check.attributes = FALSE)
```

```
> N <- 100L
> Z <- matrix(rnorm(N * J), nrow = J)
> Y <- Mult(lt, Z) + (mn <- 1:J)</pre>
```

Before we add some interval-censoring to the data, let's estimate the Cholesky factor C (here called 1t) from the raw continuous data. The true mean μ and the true covariance matrix Σ can be estimated from the uncensored data via maximum likelihood as

We first check if we can obtain the same results by numerial optimisation using $\mathtt{dmvnorm}$ and the scores $\mathtt{sldmvnorm}$. The log-likelihood and the score function (for the centered means) in terms of \mathbf{C} are

The diagonal elements of C are positive, so we need box constraints

```
> llim <- rep(-Inf, J * (J + 1) / 2)
> llim[which(rownames(unclass(lt)) %in% paste(1:J, 1:J, sep = "."))] <- 1e-4
```

The ML-estimate of \mathbf{CC}^{\top} is now used to obtain an estimate of \mathbf{C} and we check the score function for some random starting values

```
> if (BYROW) {
+   cML <- chol(Shat)[upper.tri(Shat, diag = TRUE)]
+ } else {
+   cML <- t(chol(Shat))[lower.tri(Shat, diag = TRUE)]
+ }
> 11(cML)

[1] 517.8685

> start <- runif(length(cML))
> if (require("numDeriv", quietly = TRUE))
+   chk(grad(11, start), sc(start), check.attributes = FALSE)
```

Finally, we hand over to optim and compare the results of the analytically and numerically obtained ML estimates

```
> op <- optim(start, fn = 11, gr = sc, method = "L-BFGS-B",
            lower = llim, control = list(trace = TRUE))
iter
      10 value 518.092239
      20 value 517.868548
iter
final value 517.868548
converged
> ## ML numerically

4 0.0000000 1.0954451 0.1651446 0.8790491
```

Under interval-censoring, the mean and C are no longer orthogonal and there is no analytic solution to the ML estimation problem. So, we add some interval-censoring represented by lwr and upr and try to estimate the model parameters via lpmvnorm and corresponding scores slpmvnorm.

```
> prb <- 1:9 / 10
> sds <- sqrt(diag(Sigma))
> ct <- sapply(1:J, function(j) qnorm(prb, mean = mn[j], sd = sds[j]))
> lwr <- upr <- Y
> for (j in 1:J) {
+    f <- cut(Y[j,], breaks = c(-Inf, ct[,j], Inf))
+    lwr[j,] <- c(-Inf, ct[,j])[f]
+    upr[j,] <- c(ct[,j], Inf)[f]
+ }</pre>
```

Let's do some sanity and performance checks first. For different values of M, we evaluate the log-likelihood using pmvnorm (called in lpmvnormR) and the simplified implementation (fast and slow). The comparion is a bit unfair, because we do not add the time needed to setup Halton sequences, but we would do this only once and use the stored values for repeated evaluations of a log-likelihood (because the optimiser expects a deterministic function to be optimised)

```
> M \leftarrow floor(exp(0:25/10) * 1000)
> 1GB <- sapply(M, function(m) {</pre>
      st <- system.time(ret <-
          lpmvnormR(lwr, upr, mean = mn, chol = lt, algorithm =
                     GenzBretz(maxpts = m, abseps = 0, releps = 0)))
      return(c(st["user.self"], 11 = ret))
  })
+
>
  1H <- sapply(M, function(m) {</pre>
      W <- NULL
      if (require("qrng", quietly = TRUE))
+
          W \leftarrow t(ghalton(m, d = J - 1))
      st <- system.time(ret <- lpmvnorm(lwr, upr, mean = mn,</pre>
                                           chol = lt, w = W, M = m)
      return(c(st["user.self"], 11 = ret))
+
 })
+
  1Hf <- sapply(M, function(m) {</pre>
      W <- NULL
      if (require("qrng", quietly = TRUE))
+
           W \leftarrow t(ghalton(m, d = J - 1))
      st <- system.time(ret <- lpmvnorm(lwr, upr, mean = mn, chol = lt,
                                           w = W, M = m, fast = TRUE))
      return(c(st["user.self"], 11 = ret))
+ })
```

The evaluated log-likelihoods and corresponding timings are given in Figure 4.1. It seems that for $M \ge 3000$, results are reasonably stable.

We now define the log-likelihood function. It is important to use weights via the w argument (or to set the seed) such that only the candidate parameters parm change with repeated calls to 11. We use an extremely low number of integration points M, let's see if this still works out.

```
> M <- 500
> if (require("qrng", quietly = TRUE)) {
      ### quasi-Monte-Carlo
      W \leftarrow t(ghalton(M, d = J - 1))
+ } else {
      ### Monte-Carlo
      W \leftarrow matrix(runif(M * (J - 1)), nrow = J - 1)
+ }
> 11 <- function(parm, J) {</pre>
       m <- parm[1:J]</pre>
                                         ### mean parameters
       parm <- parm[-(1:J)]</pre>
                                       ### chol parameters
       C <- matrix(c(parm), ncol = 1L)</pre>
       C <- ltMatrices(C, diag = TRUE, byrow = BYROW)</pre>
        -lpmvnorm(lower = lwr, upper = upr, mean = m, chol = C,
                   w = W, M = M, logLik = TRUE)
+ }
```

We can check the correctness of our log-likelihood function

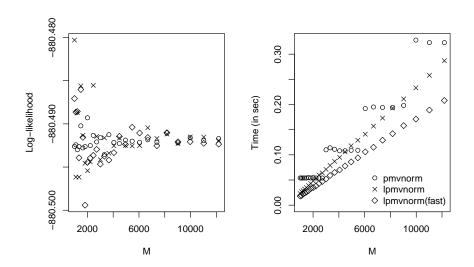

Figure 4.1: Evaluated log-likelihoods (left) and timings (right).

```
> prm <- c(mn, unclass(lt))</pre>
> 11(prm, J = J)
[1] 880.4956
> ### ATLAS gives -880.4908, M1mac gives -880.4911
> round(lpmvnormR(lwr, upr, mean = mn, chol = lt,
                   algorithm = GenzBretz(maxpts = M, abseps = 0, releps = 0)), 3)
[1] -880.491
> (11prm < - 1pmvnorm(1wr, upr, mean = mn, chol = 1t, w = W, M = M))
[1] -880.4956
> chk(llprm, sum(lpmvnorm(lwr, upr, mean = mn, chol = lt, w = W,
                            M = M, logLik = FALSE)))
   Before we hand over to the optimiser, we define the score function with respect to \mu and C
> sc <- function(parm, J) {</pre>
      m <- parm[1:J]</pre>
                                   ### mean parameters
      parm <- parm[-(1:J)]</pre>
                                   ### chol parameters
      C <- matrix(c(parm), ncol = 1L)</pre>
      C <- ltMatrices(C, diag = TRUE, byrow = BYROW)</pre>
      ret <- slpmvnorm(lower = lwr, upper = upr, mean = m, chol = C,
                        W = W, M = M, logLik = TRUE)
      return(-c(rowSums(ret$mean), rowSums(unclass(ret$chol))))
+ }
  and check the correctness numerically
> if (require("numDeriv", quietly = TRUE))
      chk(grad(11, prm, J = J), sc(prm, J = J), check.attributes = FALSE)
```

Finally, we can hand-over to optim. Because we need diag(C) > 0, we use box constraints and method = "L-BFGS-B". We start with the estimates obtained from the original continuous data.

```
> 11im < -rep(-Inf, J + J * (J + 1) / 2)
> 11im[J + which(rownames(unclass(lt)) %in% paste(1:J, 1:J, sep = "."))] <- 1e-4
> if (BYROW) {
   start <- c(rowMeans(Y), chol(Shat)[upper.tri(Shat, diag = TRUE)])</pre>
+ } else {
    start <- c(rowMeans(Y), t(chol(Shat))[lower.tri(Shat, diag = TRUE)])</pre>
> 11(start, J = J)
[1] 875.4005
> op <- optim(start, fn = 11, gr = sc, J = J, method = "L-BFGS-B",
              lower = llim, control = list(trace = TRUE))
       10 value 874.158309
final value 874.158301
converged
> op$value ## compare with
[1] 874.1583
> 11(prm, J = J)
[1] 880.4956
   We can now compare the true and estimated Cholesky factor C of our covariance matrix
\Sigma = \mathbf{C}\mathbf{C}^{\mathsf{T}}

2

0.9669828 2.1281616 2.9454002 3.9886471

Warning: Do NOT assume the choices made here (especially M and W) to be universally applicable. Make sure to investigate the accuracy depending on these parameters of the log-likelihood and score function in your application.

One could ask what this whole exercise was about statistically. We estimated a multivariate normal distribution from interval-censored data, so what? Maybe we were primarily interested in fitting a linear regression

$$\mathbb{E}(Y_1 \mid Y_j = y_j, j = 2, \dots, J) = \alpha + \sum_{j=2}^{J} \beta_j y_j.$$

Interval-censoring in the response could have been handled by some Tobit model, but what about interval-censoring in the explanatory variables? Based on the multivariate distribution just estimated, we can obtain the regression coefficients β_i as

 $> c(cond_mvnorm(chol = C, which = 2:J, given = diag(J - 1))$ \$mean)
[1] 0.2602003 0.2270392 -0.1298560

We can compare these estimated regression coefficients with those obtained from a linear model fitted to the exact observations

The estimates are quite close, but what about standard errors? Interval-censoring means loss of information, so we should see larger standard errors for the interval-censored data.

Let's obtain the Hessian for all parameters first

```
> H <- optim(op$par, fn = 11, gr = sc, J = J, method = "L-BFGS-B", + lower = llim, hessian = TRUE)$hessian
```

and next we sample from the distribution of the maximum-likelihood estimators

The standard error in this sample should be close to the ones obtained from the inverse Fisher information

```
> c(sqrt(rowMeans((rC - rowMeans(rC))^2)))
```

```
5 6 7 8 9 10 11
0.05129646 0.07989618 0.12445698 0.16089554 0.07609088 0.11566519 0.14020346
12 13 14
0.09622312 0.10415427 0.08278985
```

> c(sqrt(diagonals(Crossprod(solve(L)))))

- [1] 0.06825507 0.10816499 0.12670329 0.14073702 0.05498052 0.10839260
- [7] 0.12441885 0.14311786 0.08812684 0.11638318 0.13340466 0.09586564
- [13] 0.10450821 0.08154249

We now coerse the matrix rC to an object of class ltMatrices

```
> rC <- ltMatrices(rC, diag = TRUE)
```

The object rC contains all sampled Cholesky factors of the covariance matrix. From each of these matrices, we compute the regression coefficient, giving us a sample we can use to compute standard errors from

```
> rbeta <- cond_mvnorm(chol = rC, which = 2:J, given = diag(J - 1))$mean > sqrt(rowMeans((rbeta - rowMeans(rbeta))^2))
```

```
[1] 0.08792945 0.04869062 0.07752184
```

which are, as expected, slightly different from the ones obtained from the more informative exact observations

```
> sqrt(diag(vcov(m1)))[-1L]
```

```
Y2 Y3 Y4
0.08229627 0.05039009 0.06246094
```

Chapter 5

Continuous-discrete Likelihoods

We sometimes are faced with outcomes measured at different levels of precision. Some variables might have been observed very exactly, and therefore we might want to use the log-Lebesque density for defining the log-likelihood. Other variables might be available as relatively wide intervals only, and thus the log-likelihood is a log-probability. We can use the infrastructure developed so far to compute a joint likelihood. Let's assume we have are interested in the joint distribution of $(\mathbf{Y}_i, \mathbf{X}_i)$ and we observed $\mathbf{Y}_i = \mathbf{y}_i$ (that is, exact observations of \mathbf{Y}) and $\mathbf{a}_i < \mathbf{X}_i \leq \mathbf{b}_i$ (that is, interval-censored observations for \mathbf{X}_i). We define the log-likelihood based on the joint normal distribution $(\mathbf{Y}_i, \mathbf{X}_i) \sim \mathbb{N}_J((\boldsymbol{\mu}_i, \boldsymbol{\eta}_i)^{\top}, \mathbf{C}_i \mathbf{C}_i^{\top})$ as

$$\ell_i(\boldsymbol{\mu}_i, \boldsymbol{\eta}_i, \mathbf{C}_i) = \ell_i(\boldsymbol{\mu}_i, \mathbf{C}_i) + \log(\mathbb{P}(\mathbf{a}_i < \mathbf{X}_i \le \mathbf{b}_i \mid \mathbf{C}_i, \boldsymbol{\eta}_i, \mathbf{Y}_i = \mathbf{y}_i)).$$

The trick here is to decompose the joint likelihood into a product of the marginal Lebesque density of \mathbf{Y}_i and the conditional probability of \mathbf{X}_i given $\mathbf{Y}_i = \mathbf{y}_i$.

We first check the data

```
\langle dp \ input \ checks \ 93 \rangle \equiv
      stopifnot(xor(missing(chol), missing(invchol)))
      cJ <- nrow(obs)
     dJ <- nrow(lower)
     N <- ncol(obs)
      stopifnot(N == ncol(lower))
      stopifnot(N == ncol(upper))
      if (all(mean == 0)) {
          cmean <- 0
          dmean <- 0
     } else {
          if (!is.matrix(mean))
              mean <- matrix(mean, nrow = cJ + dJ, ncol = N)</pre>
          stopifnot(nrow(mean) == cJ + dJ)
          stopifnot(ncol(mean) == N)
          cmean <- mean[1:cJ,, drop = FALSE]</pre>
          dmean <- mean[-(1:cJ),, drop = FALSE]</pre>
     }
```

Fragment referenced in 94, 96.

We can use marg_mvnorm and cond_mvnorm to compute the marginal and the conditional normal distributions and the joint log-likelihood is simply the sum of the two corresponding log-likelihoods.

```
\langle ldpmvnorm 94 \rangle \equiv
     ldpmvnorm <- function(obs, lower, upper, mean = 0, chol, invchol,</pre>
                              logLik = TRUE, ...) {
          if (missing(obs) || is.null(obs))
              return(lpmvnorm(lower = lower, upper = upper, mean = mean,
                                chol = chol, invchol = invchol, logLik = logLik, ...))
          if (missing(lower) && missing(upper) || is.null(lower) && is.null(upper))
              return(ldmvnorm(obs = obs, mean = mean,
                                chol = chol, invchol = invchol, logLik = logLik))
          \langle dp input checks 93 \rangle
          if (!missing(invchol)) {
              J <- dim(invchol)[2L]</pre>
              stopifnot(cJ + dJ == J)
              md <- marg_mvnorm(invchol = invchol, which = 1:cJ)</pre>
              ret <- ldmvnorm(obs = obs, mean = cmean, invchol = md$invchol,</pre>
                                logLik = logLik)
              cd <- cond_mvnorm(invchol = invchol, which_given = 1:cJ,</pre>
                                  given = obs - cmean, center = TRUE)
              ret <- ret + lpmvnorm(lower = lower, upper = upper, mean = dmean,</pre>
                                      invchol = cd$invchol, center = cd$center,
                                      logLik = logLik, ...)
              return(ret)
          }
          J \leftarrow dim(chol)[2L]
          stopifnot(cJ + dJ == J)
          md <- marg_mvnorm(chol = chol, which = 1:cJ)</pre>
          ret <- ldmvnorm(obs = obs, mean = cmean, chol = md$chol, logLik = logLik)</pre>
          cd <- cond_mvnorm(chol = chol, which_given = 1:cJ,</pre>
                              given = obs - cmean, center = TRUE)
          ret <- ret + lpmvnorm(lower = lower, upper = upper, mean = dmean,</pre>
                                  chol = cd$chol, center = cd$center,
                                  logLik = logLik, ...)
          return(ret)
     }
     \Diamond
Fragment referenced in 2.
```

The score function requires a little extra work. We start with the case when invchol is given

```

Chapter 6

Unstructured Gaussian Copula Estimation

With $\mathbf{Z} \sim \mathbb{N}_J(0, \mathbf{I}_J)$ and $\mathbf{Y} = \tilde{\mathbf{C}}\mathbf{Z} \sim \mathbb{N}_J(0, \tilde{\mathbf{C}}\tilde{\mathbf{C}}^{\top})$ we want to estimate the off-diagonal elements of the lower triangular unit-diagonal matrix \mathbf{C} . We have $\tilde{\mathbf{C}}(\mathbf{C}) := \operatorname{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2}\mathbf{C}$ such that $\mathbf{\Sigma} = \tilde{\mathbf{C}}\tilde{\mathbf{C}}^{\top}$ is a correlation matrix $(\operatorname{diag}(\mathbf{\Sigma}) = \mathbf{I}_J)$. Note that directly estimating $\tilde{\mathbf{C}}$ requires J(J+1)/2 parameters under constraints $\operatorname{diag}(\mathbf{\Sigma}) = 1$ whereas only J(J-1)/2 parameters are necessary when estimating the lower triangular part of \mathbf{C} . The standardisation by $\operatorname{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2}$ ensures that $\operatorname{diag}(\mathbf{\Sigma}) \equiv 1$, that is, unconstained optimisation can be applied.

```
\langle standardize 98 \rangle \equiv
     standardize <- function(chol, invchol) {</pre>
         stopifnot(xor(missing(chol), missing(invchol)))
         if (!missing(invchol)) {
             stopifnot(!attr(invchol, "diag"))
             return(invcholD(invchol))
         stopifnot(!attr(chol, "diag"))
         return(Dchol(chol))
     }
Fragment referenced in 2.
> C <- ltMatrices(runif(10))</pre>
> all.equal(as.array(chol2cov(standardize(chol = C))),
             as.array(chol2cor(standardize(chol = C))))
[1] TRUE
> L <- solve(C)
> all.equal(as.array(invchol2cov(standardize(invchol = L))),
             as.array(invchol2cor(standardize(invchol = L))))
[1] TRUE
```

The log-likelihood function is $\ell_i(\mathbf{C}_i)$ (we omit i in the following) and we assume the score

$$\frac{\partial \ell(\mathbf{C})}{\partial \mathbf{C}}$$

is already available. We want to compute the score

$$\frac{\partial \ell(\tilde{\mathbf{C}})}{\partial \mathbf{C}}$$

which gives

$$\frac{\partial \ell(\tilde{\mathbf{C}})}{\partial \mathbf{C}} = \underbrace{\frac{\partial \ell(\tilde{\mathbf{C}})}{\partial \tilde{\mathbf{C}}}}_{=:\mathbf{T}} \times \frac{\partial \tilde{\mathbf{C}}(\mathbf{C})}{\partial \mathbf{C}}$$

We further have

$$\frac{\partial \tilde{\mathbf{C}}(\mathbf{C})}{\partial \mathbf{C}} = (\mathbf{C}^{\top} \otimes \mathbf{I}_{J}) \frac{\partial \mathrm{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2}}{\partial \mathbf{C}} + (\mathbf{I}_{J} \otimes \mathrm{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2})$$

and thus

$$\frac{\partial \ell(\tilde{\mathbf{C}})}{\partial \mathbf{C}} = \operatorname{vec}(\mathbf{I}_J \mathbf{T} \mathbf{C}^\top)^\top \frac{\partial \operatorname{diag}(\mathbf{C} \mathbf{C}^\top)^{-1/2}}{\partial \mathbf{C}} + \operatorname{vec}(\operatorname{diag}(\mathbf{C} \mathbf{C}^\top)^{-1/2} \mathbf{T} \mathbf{I}_J)^\top$$

and with

$$\frac{\partial \operatorname{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2}}{\partial \mathbf{C}} = \frac{\partial \operatorname{diag}(\mathbf{A})^{-1/2}}{\partial \mathbf{A}} \Big|_{\mathbf{A} = \mathbf{C}\mathbf{C}^{\top}} \frac{\partial \mathbf{C}\mathbf{C}^{\top}}{\partial \mathbf{C}}$$

$$= -\frac{1}{2} \operatorname{diag}(\operatorname{vec}(\operatorname{diag}(\mathbf{C}\mathbf{C}^{\top})^{-3/2})) \left[(\mathbf{C} \otimes \mathbf{I}_{J}) \frac{\partial \mathbf{C}}{\partial \mathbf{C}} + (\mathbf{I}_{J} \otimes \mathbf{C}) \frac{\partial \mathbf{C}^{\top}}{\partial \mathbf{C}} \right]$$

we can write

$$\mathrm{vec}(\mathbf{I}_J\mathbf{T}\mathbf{C}^\top)^\top(-\frac{1}{2})\mathrm{diag}(\mathrm{vec}(\mathrm{diag}(\mathbf{C}\mathbf{C}^\top)^{-3/2})) \quad = \quad -\frac{1}{2}\times\mathrm{vec}(\mathbf{I}_J\mathbf{T}\mathbf{C}^\top)^\top\times\mathrm{vec}(\mathrm{diag}(\mathbf{C}\mathbf{C}^\top)^{-3/2})^\top =: \mathbf{b}^\top$$

thus

$$\frac{\partial \ell(\tilde{\mathbf{C}})}{\partial \mathbf{C}} = \mathbf{b}^{\top} \left[(\mathbf{C} \otimes \mathbf{I}_J) \frac{\partial \mathbf{C}}{\partial \mathbf{C}} + (\mathbf{I}_J \otimes \mathbf{C}) \frac{\partial \mathbf{C}^{\top}}{\partial \mathbf{C}} \right] + \text{vec}(\text{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2}\mathbf{T}\mathbf{I}_J)^{\top} \\
= \text{vec}(\mathbf{I}_J \mathbf{B}\mathbf{C})^{\top} + \text{vec}(\mathbf{C}^{\top} \mathbf{B}\mathbf{I}_J)^{\top} \frac{\partial \mathbf{C}^{\top}}{\partial \mathbf{C}} + \text{vec}(\text{diag}(\mathbf{C}\mathbf{C}^{\top})^{-1/2}\mathbf{T}\mathbf{I}_J)^{\top}$$

when $\mathbf{b} = \text{vec}(\mathbf{B})$. These scores are implemented in destandardize with $\text{chol} = \mathbf{C}$ and $\text{score_schol} = \mathbf{T}$. If the model was parameterised in $\mathbf{L} = \mathbf{C}^{-1}$, we have $\text{invchol} = \mathbf{L}$, however, we would still need to compute \mathbf{T} (the score with respect to \mathbf{C}).

```
\langle destandardize 100 \rangle \equiv

```

We can now set-up the log-likelihood and score functions for a Gaussian copula model. We start with the classical approach of generating the marginal observations \mathbf{Y} from the ECDF with denominator N+1 and subsequent use of the Lebesque density as likelihood.

```
> data("iris")
> J <- 4</pre>
```

```
> Z <- t(qnorm(do.call("cbind", lapply(iris[1:J], rank)) / (nrow(iris) + 1)))</pre>

```

This approach is of course a bit strange, because we estimate the marginal distributions by nonparametric maximum likelihood whereas the joint distribution is estimated by plain maximum likelihood. For the latter, we can define the likelihood by boxes given by intervals obtained from the marginale ECDFs and estimate the Copula parameters by maximisation of this nonparametric likelihood.

```
> lwr <- do.call("cbind", lapply(iris[1:J], rank, ties.method = "min")) - 1L

Appendix

This document uses the following matrix derivatives

$$\frac{\partial \mathbf{y}^{\top} \mathbf{A}^{\top} \mathbf{A} \mathbf{y}}{\partial \mathbf{A}} = 2\mathbf{A} \mathbf{y} \mathbf{y}^{\top}
\frac{\partial \mathbf{A}^{-1}}{\partial \mathbf{A}} = -(\mathbf{A}^{-\top} \otimes \mathbf{A}^{-1})
\frac{\partial \mathbf{A} \mathbf{A}^{\top}}{\partial \mathbf{A}} = (\mathbf{A} \otimes \mathbf{I}_{J}) \frac{\partial \mathbf{A}}{\partial \mathbf{A}} + (\mathbf{I}_{J} \otimes \mathbf{A}) \frac{\partial \mathbf{A}^{\top}}{\partial \mathbf{A}}
= (\mathbf{A} \otimes \mathbf{I}_{J}) + (\mathbf{I}_{J} \otimes \mathbf{A}) \frac{\partial \mathbf{A}^{\top}}{\partial \mathbf{A}}
\frac{\partial \operatorname{diag}(\mathbf{A})}{\partial \mathbf{A}} = \operatorname{diag}(\operatorname{vec}(\mathbf{I}_{J}))
\frac{\partial \mathbf{A}}{\partial \mathbf{A}} = \operatorname{diag}(I_{J^{2}})
\frac{\mathbf{y}^{\top} \mathbf{A} \mathbf{y}}{\partial \mathbf{y}} = \mathbf{y}^{\top} (\mathbf{A} + \mathbf{A}^{\top})$$

and the "vec trick" $\operatorname{vec}(\mathbf{X})^{\top}(\mathbf{B} \otimes \mathbf{A}^{\top}) = \operatorname{vec}(\mathbf{A}\mathbf{X}\mathbf{B})^{\top}$.
